# Appendix to: <br> "Commodity Exports, Invisible Exports and Terms of Trade for the Middle Colonies, 1720 to 1775" 

Peter C. Mancall (University of Southern California)<br>Joshua L. Rosenbloom (University of Kansas and NBER)<br>Thomas Weiss (University of Kansas and NBER)

#### Abstract

This Appendix collects the data underlying new estimates of commodity exports, invisible exports and the impact of changes in the terms of trade on the exports of the colonies and states of the Middle Atlantic region between 1720 and 1800 and documents the methods used to construct estimates of these series from the data.

This research was funded in part by the National Science Foundation Grant SES0317265.

Our estimates of exports from the Middle Colonies are comprised of three parts: base year values for 1768-72, extrapolation of the base year values backward to 1720, and a separate set of estimates constructed for the years after 1790.

James Shepherd compiled estimates of the value of colonial exports for the base years of 1768-1772 based on data collected in the American Inspector General's Ledgers. These records, which were compiled by the American Board of Customs, recorded the quantities of all commodities legally exported from and imported into 42 colonial port districts throughout the British North American mainland from January 5, 1768 through January 5, 1773. According to Shepherd and Walton (1972, p. 204) they "represent the only period for which we have data that purport to be a complete coverage of colonial overseas trade." Shepherd (1969) and Shepherd and Walton (1972) have provided extensive analysis of these data including compilation of estimates of the value of individual commodities exported from different ports and the aggregation of these data into broader geographic regions.

We begin by presenting in more detail what is known about commodity exports in the base years and our approach to estimating the value of exports in the base years. The second section describes our extrapolation procedures for the years prior to 1768 . The third section describes the construction of estimates for 1790 and after. Commodity exports constituted only a portion of total regional exports in these years, however. Freight charges and other merchant services—so-called "invisible exports"-constituted another important source of export earnings. Although they are more difficult to measure than commodity exports, the magnitude of these earnings makes it essential to attempt to estimate them. In the fourth section we present the available evidence underlying our conjectures about the magnitude of invisible exports. In the fifth section we discuss changes in the terms of trade that influenced the purchasing power of regional export earnings. Finally we report the key export series.

## The Base Year Value of Exports

Table 1 reports the average annual value in pounds sterling of exports by source and destination between 1768 and 1772. New York and Pennsylvania were the primary sources of regional exports, accounting for fully $96.5 \%$ of the value of regional exports. Close to three-quarters of regional exports went to the West Indies or Southern Europe, while most of the rest was destined for Great Britain or Ireland. Trade with Africa was quite limited.

Table 2 documents the composition of the region's exports, showing the average quantity exported per year, and the value of these exports in pound sterling for the years 1768-1772 of selected commodities. In addition, it reports the average annual value of all exports from the two colonies (New York and Pennsylvania) that exported almost all of the region's exports. By far the most important regional export was bread and flour, which accounted for close to three fifths of regional export earnings. Adding unprocessed wheat, it is possible to account for about two thirds of total earnings. Including the other listed commodities we can account for almost all of regional export earnings. For Pennsylvania the enumerated commodities amounted to $95 \%$ of total export earnings, while for New York this figure was 89\%. Given the greater volume of exports produced by Pennsylvania, the enumerated commodities accounted for $93 \%$ of total regional export earnings between 1768 and 1772.

As Table 2 makes clear, although the Middle Colonies produced a diverse array of exports, a relatively small subset of commodities accounted for the bulk of the value of exports in the base years. Indeed the ten commodities listed in table 2 make up well over 90 percent of export values in contemporary prices.

We revalued these exports in 1840 prices for use in extrapolating to other years. We used 1840 prices because we want a series that can eventually be linked to comparable series for the nineteenth century. Monthly quotations of the 1840 prices for all of these commodities, except flaxseed, are available in 1840 in Cole (1938). We collected price data for both Philadelphia and New York from this source, averaged the monthly values to create an annual figure, and then averaged across the two cities to get a single value for each commodity.

In constructing a constant price series of exports we are in effect allowing differences in relative prices to determine the relative importance of different commodities within our aggregate series. If relative prices are highly unstable than the choice of the base year that we use may substantially influence the resulting estimates. Fortunately, however, this does not appear to be the case here. Table 3 summarizes the 1840 price data and compares the relative prices that they imply to the 1768-1772 sterling values. Relative prices in the two years had a correlation coefficient of over 0.98.

To estimate the average annual value of exports between 1768 and 1772 in prices of 1840, we first calculated the value of those exports for which prices were available in 1840 by multiplying the average annual quantity of each commodity exported to each destination by its 1840 price, and summed these figures. Then, to account for commodities for which prices were not available, we inflated the resulting total by dividing by the share of priced exports in the total value of all exports. This process is summarized in Table 4, which shows that in 1840 prices exports had an average annual value of $\$ 2.1$ million from Philadelphia, and $\$ 995$ thousand from New York.

## Extrapolation of base year values

In contrast to the detailed picture of the Middle Colonies trade that can be constructed for the end of the colonial period it is hard to find comprehensive quantitative data for earlier years. During the eighteenth century naval officers in American ports compiled quarterly reports of all ships clearing and entering colonial ports along with details of the cargos they carried. While a large number of these naval officers' lists have been preserved, their coverage for most ports is spotty and incomplete. ${ }^{1}$ A number of scholars have been able to piece together data on the quantities of exports of specific commodities from Philadelphia for scattered years, but these data are too sparse and inconsistent to allow a reconstruction of the volume of trade earlier in the century. Helen Klopfer’s (1936) dissertation assembled data on exports of wheat, flour, bread, and corn
${ }^{1}$ McCusker (2006) provides a good introduction to these data, but see also Price (1984). Louis Harper undertook the collection and systematic analysis of the data found in the naval officers list, but most of these data remains only partially accessible in the Harper archives located at the University of California, Davis.
for most years after 1760, but she was able to obtain only scattered observations for a few earlier years. Lydon (1967) reports data for a few years in the early 1730s, but these are not entirely consistent with those found in Klopfer's work. Shepherd and Williamson (1972, p. 170) summarized what can be gleaned about exports of bread and flour from New York from the Naval Officers lists analyzed by Louis Harper. Their tables indicate that with the exception of data for 1733-1735, there are only a few scattered years with usable data. There are no data in this source for Philadelphia, as the records from this port appear to have been destroyed at some point in the nineteenth century. Data for other ports are available only for scattered years, or for only one or two quarters in some years, making it difficult to construct consistent and complete records of colonial exports. ${ }^{2}$

Consequently it is necessary to infer changes in the volume of trade from other sources. The most complete data set is that for colonial exports to England. British customs inspectors compiled records of all arrivals in English and Welsh ports beginning in 1696 and Scottish ports beginning in 1740. These data were compiled at the time into annual ledgers listing the value of imports arriving from and exports leaving for different trading areas. Rather than using current prices, however, the compilers of these ledgers used a set of official values that reflected prices near the beginning of the eighteenth century. As a result these series are best interpreted as fixed-price indexes of the volume of trade (McCusker 2006, pp. 641-43).

To construct estimates of exports to Great Britain we first construct three-year centered moving averages of the value of English imports from New York and Philadelphia. We use a centered moving average because of time lags between departure from colonial ports and arrivals in England. Averaging also helps to smooth short-run fluctuations in the import series. We then use the year-to-year changes in this series to extrapolate the value of exports in the base years backward in time. Formally, our estimating equation can be expressed as

[^0]$$
\mathrm{V}_{\mathrm{jb}}(\mathrm{t})=V_{j b}^{*}\left\lfloor\sum_{T=1-1}^{t+1} \frac{I_{j}(T)}{3 I_{j}^{*}}\right\rfloor
$$

Where $\mathrm{V}_{\mathrm{jb}}(\mathrm{t})$ is the value in 1840 prices of exports to Great Britain in year t from colony $\mathrm{j}, \mathrm{V}{ }_{\mathrm{jb}}$ is the base year value of exports to Great Britain from colony $\mathrm{j}, \mathrm{I}_{\mathrm{j}}(\mathrm{t})$ is the constant price index of the value of imports into Britain from colony $j$ in year $t$, and $I^{*}{ }_{j}$ denotes the base year values in constant price sterling.

This approach could not be used to estimate colonial exports to other destinations because the necessary annual data are not available. Instead we relied on changes in the outward tonnage clearing each of the major Middle Colony ports to extrapolate exports to these places. Even this method has its shortcomings as tonnage data are not available continuously. But as Tables 5 and 6 indicate, data on tonnage clearing both Philadelphia and New York are available for dates spanning much of the period from 1715 to 1772. The majority of these data have been compiled in Historical Statistics of the United States, but we have expanded the coverage of these data with additional information on tonnage from Philadelphia from 1720 to 1740 in Lydon (1967).

We use the tonnage data to construct an index of the volume of exports from each port to each destination and use this index to extrapolate the base year values for exports from each port to each destination in these benchmark years. The estimating formula is

Where $\mathrm{V}_{\mathrm{ji}}(\mathrm{t})$ denotes the value of exports from colony j to destination i in year $\mathrm{t}, \mathrm{T}_{\mathrm{ji}}(\mathrm{t})$ is tonnage clearing from colony $j$ to destination $i$ in year $t$, and $\mathrm{V}^{*}$ and $\mathrm{T}^{*}$ denote the average annual value of exports and tonnage clearing, respectively, in the base years. We then interpolated between benchmark years by assuming that tonnage, and hence the value of exports, to each destination changed at a constant annual rate equal to the rate of change between each set of benchmark values.

This approach assumes that the ratio of cargo values to tonnage remained constant over the period from 1720 through 1772. The validity of this assumption cannot be directly evaluated except in the case of exports to England. In this one case we can compare the value of colonial exports (the constant sterling value of English imports) to the tonnage clearing for Great Britain at various dates. We report these data in Table 7.

There is considerable year-to-year variability in the respective series making it difficult to discern a trend. If anything, however, based on a comparison of the average value per ton before 1735 and after 1768, the value per ton appears to have been falling over time. If this were true for other destinations then our assumption of constant value per ton would impart an upward bias to our estimates of the growth of exports over the period 1720-1772.

Having constructed both benchmark figures and an annual series from New York and Philadelphia to each destination, we sum exports for each port in each year across destinations and then combine the series for New York and Philadelphia. Finally, we adjust the resulting total to reflect the $3.5 \%$ of regional exports that originated in New Jersey and Delaware.

## Exports after 1776

## Data availability

Because of the disruption caused by the Revolution there are no reliable export statistics for the Middle Atlantic states until the 1790s. For the period from 1791 to 1809 we used data on the nominal value of exports by state in conjunction with an index of regional export prices to construct a series of exports in constant, 1840 prices.

Pitkin (1816) reported the value of foreign exports annually by state beginning in 1791. Beginning with data for 1803 he reported separately the value of re-exports and domestically produced exports from each state. Between 1791 and 1802 Pitkin reported the value of domestically produced exports only at the national level, and not by state. From 1791 to 1795 domestically produced exports constituted more than 95 percent of total exports, but thereafter the share of re-exports increased substantially, so that by 1800 only about 30 percent of US exports were produced domestically. Thus it is necessary for us to adjust the available state totals to account for this difference.

## Methodology

Denote the value of domestically produced exports by D , total exports by X , the ratio of domestic to total exports in state j by $\theta_{\mathrm{j}}$, and the ratio of domestic to total exports in the US by $\theta$. Then

$$
\mathrm{D}_{\mathrm{j}}=\theta_{\mathrm{j}} * \mathrm{X}_{\mathrm{j}}
$$

Multiplying and dividing by $\theta$, and rearranging terms

$$
\mathrm{D}_{\mathrm{i}}=\left(\theta_{\mathrm{j}} / \theta\right) * \theta \mathrm{X}_{\mathrm{j}}
$$

In other words the value of domestic exports for state j is equal to total exports times the national share of domestically produced exports, times the ratio of the state to the national shares of domestically produced exports.

For the period from 1791 to 1802 we do not know the value of $\left(\theta_{j} / \theta\right)$, so for each state we substitute the average value from 1803 through 1810. In the case of New Jersey, where $\left(\theta_{\mathrm{j}} / \theta\right)^{*} \theta$ yields a value greater than 1 we assume that all exports were domestically produced.

This procedure allows us to construct estimates in prices of 1790-1809 of exports from each state in the Middle Atlantic. We then use an index of export prices to convert this figure to constant 1840 prices. Price data are more numerous for Philadelphia than for New York, so we use Philadelphia prices to construct our index. For periods when we were able to compare price movements in New York with those in Philadelphia, the indexes moved quite similarly.

## Nominal and Real Export Values 1790-1808

Table 8 reproduces Pitkin's data on the value of total and domestically produced exports from each state in the Middle Atlantic, along with figures for all states combined. Table 9 reports our estimates of domestically produced exports in current prices for each state and for the region over the entire period.

Table 10 reports data on individual commodity prices in Philadelphia and shows two export price indexes based on these data: one constructed as an weighted index of export commodity prices, the other as an unweighted index, where weights reflect the
relative shares of export value accounted for by each commodity in the period 17681772. In addition Table 10 reproduces McCusker's composite consumer price index for the US. Each index is set equal to 100 in 1840.

After 1800 all three price indices behave roughly the same. From 1791 to 1799, however, the composite commodity index behaves very differently from the two export price indices. While the export price data suggest that prices in the 1790s were higher on average than in the 1840s, the composite price index implies that the general price level was considerably lower in this period than in 1840. As a result, use of the composite index would yield higher real values in the early years of the 1790s, but slower growth of real exports over the decade.

The export price series seem more appropriate indices for deflating exports than the broader composite index, and the weighted series should be the better reflection of price trends for an aggregate series than the unweighted series. Thus, we used the weighted export price index to convert the current price series to one valued in prices of 1840. The resulting constant price export series is reported in Table 11

## Invisible Exports

An important feature of our estimates is the inclusion of invisible earnings in the export totals for the region. Table 12 summarizes estimates compiled by James F. Shepherd and Gary M. Walton (1969) for the years 1768-1772 of earnings from shipping and other services related to the Middle Colonies external trade. These data reveal that exports of shipping and other commercial services from the Middle Colonies were a major source of export earnings, generating income worth nearly 44 percent of the value of the region's commodity exports. These earnings were comprised mostly of freight earnings, which equaled 30.6 percent of commodity exports, with other invisible service income amounting to 13 percent of commodity exports. Earnings from these so-called "invisible" exports were highest in the trade with Great Britain and Ireland, where they reached nearly 50 percent of the value of commodity exports; and lowest in the trade with Southern Europe and the Wine Islands, where they amounted to 34 percent of the value of visible trade.

Given the importance of invisible earnings, it seemed imperative that we include estimates of their value in our measure of the trade sector. The addition of those values, even if estimated imprecisely, would improve considerably the overall level of earnings generated by the region's export sector. To the extent we can gauge changes in the importance of invisible earnings over time, however roughly, we will have a better sense of the extent to which this sector's earnings drove economic growth in the region.

## Invisible Exports 1715-1776

Invisible earnings depended on several things. At a point in time the invisible earnings that accrued to Middle colonists were a function of the earnings rate on each route (that is the ratio of invisible earnings to the value of the commodity exports), the volume of commodity exports on each route, and the share of tonnage engaged in the export trade owned by colonists in the region. The earnings accruing to Middle colonists would change over time as these variable changed. ${ }^{3}$ While we have evidence on the changing importance of routes over time, our evidence on the earnings rate by route pertain to only the end of the colonial period. That is we do not know how the ratio of invisible to visible exports changed over time. Moreover, while we have some evidence on ownership shares, it is not sufficient to establish a precise picture of changes in those shares over time. Nevertheless, the evidence does suggest the broad outline of ownership shares over time.

Shepherd and Walton (1969, Table 3, pp. 99-100) present evidence on the average ownership shares for the period 1715-43 to 1763-65. For the Middle Colonies the evidence came entirely from New York and indicated that residents of the Middle Colonies owned 9 percent of the tonnage entering from Great Britain into the Northern colonies, and 1 to 2 percent of the tonnage entering into the South, and 2 percent of the clearances. Their shares were larger for the entrances from Southern Europe (15 percent into the Northern colonies) and the West Indies (14 percent into the Northern colonies, 1 percent into New England, 6 percent into the Lower South). Only in the latter region did

[^1]they own much of the tonnage clearing for any destination. In the trade with the West Indies, they owned 3 percent of tonnage clearing the Northern colonies, 1 percent clearing from New England, and10 percent clearing from the Lower South. Although their figures are based on observations throughout the $18^{\text {th }}$ century, Shepherd and Walton reported only the average values, suggesting that they did not find compelling evidence of a trend in ownership shares. ${ }^{4}$

On the other hand, the traditional story about the Middle colonies is one that features a growing role of colonial merchants in trans-Atlantic trade, which would suggest that the importance of invisible earnings was growing over time. The key questions are whether it did increase, and if so by how much. The upper bound of such growth would seem to be that implied by the data on ownership of tonnage registered in Philadelphia in 1726-29 and 1770-75, reproduced in Table 13. McCusker's figures indicate that the share owned by residents of the Middle Colonies grew from 57 percent at the earlier date to 83 percent by the latter date. ${ }^{4}$ This increase implies an annual average rate of growth of the share of tonnage owned in the region of 0.83 percent. This rate of increase would seem to be the upper bound, as suggested by the following evidence.

The 0.83 percent rate we have inferred from McCusker's data is far higher than the rate of increase indicated by the rise in the shares of tonnage registered in Pennsylvania that were owned by residents of the Delaware Valley. According to Simeon Crowther (1973, Table 8, p. 100), that share rose from 68 percent in 1727 and 1730 to 76 percent in 1773-75, having peaked at 85 percent in 1754-57. McCusker and

[^2]Crowther appear to have used the same source, so the discrepancy is hard to explain. The differences in shares are not very large at the end of the period, although McCusker's ending share of 83 percent for the period 1770-75 is higher than either of the two shares Crowther shows for the same time period: 82 percent for 1769-72 and 76 percent for 1773-75. On the other hand, McCusker’s initial share of 57 percent for 1726-29 is fully 10 percentage points lower than Crowther's 68 percent for 1727 and 1730. Crowther's series has the advantage that it shows fuller coverage over the entire period, and thus might be a preferred series. In both cases, however, the figures pertain to registered tonnage, and do not reflect the intensity of usage of the tonnage or usage by route.

Gary Walton has presented evidence on the use of tonnage owned by Middle Colonists in trade with Barbados and Jamaica, which is summarized in Table 13. If one looks at only the trade between the Middle colonies and Barbados and Jamaica, there was a slight increase in the Middle Colonies' ownership share between the end of the 17th century and the end of the colonial period, but essentially no change between 1729-31 and the end of the colonial period (Walton 1968, Tables 3-7, pp. 372-81). Of the 7,366 tons that entered and cleared Barbados and Jamaica in the period 1697-98 to 1716, the Middle Colonies owned 5,428 tons or 74 percent. This share rose to 80 percent in the period 1729-31 to 1736, and then dipped slightly to 79 percent in 1764 and 1773. Overall the region's ownership share of shipping on this trade route rose by less than 10 percent over nearly the whole of the colonial period, but declined at an annual rate of 0.02 percent per year after 1729-31. On the other hand, if we look at the trade between Barbados and Jamaica and all destinations, the Middle Colonies' ownership share rose more noticeably, although after 1729-31 it did not increase quite as much as shown in the McCusker series, having risen at 0.75 percent per year.

Clearly more work is needed to reconcile these diverse pictures of ownership in order to gain a more secure estimate of the trend in ownership and its implications for earnings from the shipping trade. That, however, is future work. For now, it would seem the increase in the Middle Colonists’ ownership share must have fallen somewhere between 0.0 percent per year, as implied by Shepherd and Walton, and 0.83 percent per year implied by McCusker. We have used the mid point of that range as the best estimate. Specifically, to estimate invisible earnings for the region we assume that $\mathrm{S}_{\mathrm{j}}$ -
the ratio of invisible to visible earnings to each destination j -was the same for both New York and Philadelphia, equal to the regional value implied by Shepherd and Walton's estimates for the end of the colonial period, and that the ratio had increased over time for the region at 0.4 percent per year. Thus our estimate of invisible earnings from colony i , to destination j in year t is

## 区

We then sum these destination specific estimates for New York and Philadelphia, and inflate them, as we did for the value of visible exports, to produce estimates for the region as a whole.

## Invisible Earnings 1790-1810

In order to estimate invisible earnings for the period after 1790 we converted Douglass North's estimate of freight earnings for the U.S. for 1790-1819 in current prices to a series valued in 1840 prices, and estimated the share of those earnings that accrued to the Middle Atlantic states. The data are shown in Appendix Table 14.

North (1960, Tables A-3 and B-2 and 1961, Table Q-VIII, p. 245) estimated his freight earnings as the product of earnings per ton and gross registered tonnage, where the latter figures were adjusted for the removal of 'ghost tonnage." This stock figure was then multiplied by an "Activity Index" to gauge fluctuations in use; the index being equal to the gross registered tonnage divided by net tonnage entering US ports. The adjusted series on tonnage was then multiplied by a freight rate index in order to gauge changes in rates. Dollar values were obtained by weighting the adjusted series by an estimate of earnings per ton (\$50) in the base year of 1796-1800. Because the freight rate index captures changes in nominal rates over time, this calculation yields freight earnings in current prices.

To obtain the series in 1840 prices, we deflated the nominal net freight earnings by North's Freight Rate Index which we had shifted to a base of 1840 . We first shifted his index series running from 1815 to 1860 on a base of 1830 to a base of 1840 , then extended that series back to 1790 .

The Mid Atlantic share of the nation's freight earnings was estimated based on the region's share of registered tonnage employed in foreign trade (New American State Papers, Commerce and Navigation, vol. 4 pp. 450-52). Those data were not available for 1790-92, or for 1809. This share was, however, quite stable over the period 1793-1808, and very close to the share of 29 percent implied by the data reported in Shepherd and Walton (1969, Tables 1, 6, 7). For 1791-92 we used the 1793 share of 29 percent, while for 1809 we assumed the region's share was 30 percent, the average share for the years 1806-1808.

These calculations yielded a 1790 value of gross freight earnings (in 1840 prices) for the U.S. of $\$ 4.5$ million (compared to North's estimate of 5.9 million in prices of 1796-1800). The Mid Atlantic share of net freight earnings (gross less foreign port charges) was estimated as 29 percent and amounted to $\$ 1.05$ million, a figure very much in line with our estimate of $\$ 1.12$ million average for 1768-72.

To incorporate other service income originating in foreign trade we inflated the earnings figures to include other service income earned in foreign trade using the ratio (0.43) of other service income to freight earnings implied by Shepherd and Walton's calculations for 1768-1772.

## Terms of Trade

To measure the terms of trade we construct an index of prices of major exports from the Middle Colonies and compare it to the Gilboy-Schumpeter index of British prices (Schumpeter 1938).

The Gilboy-Schumpeter index is reported for crop years, which are denoted by the year in which they begin. Thus the figure reported for 1699 is for prices begining in October 1699 and running through September 1700. To convert these figures to calendar years we construct a weighted average, so that our calendar year 1700 data are computed as 0.75 times the Gilboy-Schumpeter estimate for 1699 plus 0.25 times the figure for 1700. Schumpeter (1938) reports two indexes, one for consumer goods and one for producer goods. We combine these into a single unweighted average.

For the colonial period we use data reported in McCusker (2006, Eg 251-259) to construct a weighted index of the prices of flour (.87), wheat (.10), and pork (.03)
between 1720 and 1775. To extend the series back to 1700 we use an index based on the prices of flour (.89) and wheat (.11). To extend the series forward after 1775 we use prices reported in Cole (1938) to construct a weighted average (weights in parentheses) of the prices of wheat (0.065), bread (0.358), flour (0.358), beef (0.014), pork (0.014), staves (0.043) and bar iron (0.034).

Table 15 reports the indexes of export and import prices and their ratio over the period 1700-1800, with the index set equal to 100 for the base years 1768-1772.

## Middle Colony Exports

In Table 16 we report all the key series described above: benchmark figures for commodity exports from New York and Pennsylvania, the annual series on commodity exports from New York, Pennsylvania, and the region, an annual series on invisible earnings for the region, and the terms of trade. We also report total exports (commodity exports plus invisible earnings) both with and without adjustment for changes in the terms of trade.

## Appendix Table 1

Average Annual Value of Exports by Colony of Origin and Destination, 1768-1772

| Colony of Origin | Destination |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Great <br> Britain | Ireland | Southern Europe and Wine Islands | West Indies | Africa | Row Total |
| Annual Average Value of Exports in Pounds Sterling, 1768-1772 |  |  |  |  |  |  |
| New York | 42,867 | 25,953 | 35,642 | 68,375 | 783 | 173,620 |
| New Jersey | 68 | 25 | 210 | 1,941 |  | 2,244 |
| Pennsylvania | 19,994 | 25,752 | 143,362 | 140,806 | 294 | 330,208 |
| Delaware |  | 3,590 | 12,489 |  |  | 16,079 |
| Column Total | 62,930 | 55,320 | 191,704 | 211,121 | 1,077 | 522,151 |
| Percentage of Exports Originating in Each Colony (column percentages) |  |  |  |  |  |  |
| New York | 68.1 | 46.9 | 18.6 | 32.4 | 72.7 | 33.3 |
| New Jersey | 0.1 | 0.0 | 0.1 | 0.9 | 0.0 | 0.4 |
| Pennsylvania | 31.8 | 46.6 | 74.8 | 66.7 | 27.3 | 63.2 |
| Delaware | 0.0 | 6.5 | 6.5 | 0.0 | 0.0 | 3.1 |
| Column Total | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Percentage of Exports Going to Each Destination (row percentages) |  |  |  |  |  |  |
| New York | 24.7 | 14.9 | 20.5 | 39.4 | 0.5 | 100.0 |
| New Jersey | 3.0 | 1.1 | 9.4 | 86.5 | 0.0 | 100.0 |
| Pennsylvania | 6.1 | 7.8 | 43.4 | 42.6 | 0.1 | 100.0 |

Appendix Table 3
Comparison of Prices of Exported Commodities, 1768-72 and 1840

|  |  | 1840 Prices |  | 1768-72 prices |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | \$ s | Index | £ s | Index |
| flour | tons | 59.20 | 100 | 10.55 | 100 |
| Bread | tons | 77.39 | 130.7 |  |  |
| beef | bbl | 13.54 | 22.9 | 2.1 | 19.8 |
| Pork | bbl | 15.48 | 26.1 |  |  |
| Flaxseed | bu | 1.05 | 1.8 | 0.2 | 1.8 |
| Grain--Indian corn | bu | 0.55 | 0.9 | 0.1 | 0.7 |
| Grain--Wheat | bu | 1.07 | 1.8 | 0.2 | 1.9 |
| Iron, bar | tons | 78.13 | 132.0 | 15.1 | 142.9 |
| Iron, pig | tons | 32.70 | 55.2 | 5.0 | 47.2 |
| Potash | tons | 111.33 | 188.1 | 25.1 | 237.6 |
| Wood Products, Staves and headings | 1000s | 32.65 | 55.1 | 3.0 | 28.0 |

Notes and sources: Prices in 1768-1772, Shepherd (1969) ; prices in 1840, Cole (1938), Town and Rasmussen (1960, p, 310) for flaxseed. Sterling prices are calculated by dividing export values by quantities for each year and averaging. Shepherd (1969) used the price of flour to value bread and flour, and the price of beef to value beef and pork. All prices are expressed in terms of dollars or pounds sterling.

Appendix Table 4
Average Annual Value of Exports by Destination, 1768-1772
(Valued in Prices of 1840)

|  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Value of | Ratio: Total |  | Base Year | Export Value |
| Itemized | Exports to |  | Shipping | per Ton |
| Commodities | Itemized | Inflated value | Tonnage | (1840 prices) |

From Philadelphia to:

| Great Britain | $\$ 100,776$ | 1.49 | $\$ 150,207$ | 3,547 | $\$ 42.35$ |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Ireland | $\$ 161,659$ | 1.03 | $\$ 166,509$ | 3,481 | $\$ 47.84$ |
| So. Europe | $\$ 808,523$ | 1.01 | $\$ 813,343$ | 9,152 | $\$ 88.87$ |

Notes and sources: Cole (1938) and McCusker (1999). The weights used in constructing the weighted index reflective the relative value of each commodity in total exports valued in current prices in 1768-1772. The weights are (in parentheses): wheat ( 0.083 ), bread (0.391), flour (0.391), staves (0.055), beef (0.018), pork (0.018), bar iron (0.044). According to Cole (1938) an M is 1200 staves, a barrel of beef weighed 225 lbs . and a barrel of pork weighed 217 lbs .

Notes: We have assumed that tonnage reported for other continental colonies' was owned by shippers in one of the Middle Colonies, most likely New York which was not shown separately in McCusker's data. We have used the year 1700 to represent the data reported by Crowther for 1685-88, 1697-98 and 1716. Crowther specifed that his data are the shares for those whose residences were known, that some residents could have owned tonnage of vessels registered at other ports, and the figures exclude re-registrations. He did not report tonnage registered for the various time periods, but did report tonnage produced by year which we summed for the pertinent years to get the figures reported in this table.

[^0]:    ${ }^{2}$ See Shepherd and Walton (1972, p. 167-75) for a compilation of some of these data and a discussion of what can be learned from them.

[^1]:    ${ }^{3}$ In our calculations we assumed that the earnings rate by route were the same for ships entering and clearing both Philadelphia and New York.

[^2]:    ${ }^{4}$ This is our inference from their presentation of the data; they did not explicitly state that there was no trend.
    ${ }^{4}$ In 1726-29, Philadelphia residents owned 47 percent of registered tonnage, while residents of Delaware and New Jersey owned another 7.5 percent. Residents of all other North American colonies owned another 2.8 percent. At the end of the colonial period Philadelphia residents owned 76.6 percent of registered tonnage, while New Jersey and Delaware residents owned another 3 percent. John J. McCusker (1972, p.154, Table 3). In our compilation of his statistics, we assigned the tonnage listed for other continental colonies to the Middle colonies total. We assumed it was owned by shippers in one of the Middle Colonies, most likely New York which was not identified separately in McCusker's data.
