Abstract

This paper studies the expansion in time and space of the multinational enterprise (MNE). Using a long panel of US MNEs, we document that: MNE affiliates grow by exporting to new markets; MNE affiliates' activities persist during the affiliate's life, usually starting with sales to the local market and eventually adding exports; and MNE affiliates' entry into new locations does not depend on the location of preexisting affiliates. Informed by these facts, we develop a multi-country quantitative dynamic model of the MNE that features heterogeneity in firm-level productivity, persistent aggregate shocks, and a rich structure of costs that affect MNE expansion. Importantly, MNE affiliates can decouple their location of production from the one of sales, and endogenously choose to enter or exit both the host and the export markets. We retain the tractability of the model by introducing a compound option formulation, which allows us to calibrate the model to detailed firm-level data, and quantify the costs to MNE expansion. Our quantitative application to a Brexit shock reveals that export platforms are important to understand the reallocation of MNE activity in time and space, and that the nature of the frictions to MNE activities, as well as endogenous price adjustments, matter for the affiliates' aggregate dynamics.

JEL Codes: F1.

Key Words: Multinational firms, Foreign direct investment, Firm dynamics, Sunk costs.

*We thank our discussants Maggie Chen, Javier Cravino, Ana Maria Santacreu, Michael Sposi, and Stephen Yeaple for very helpful comments in more than one occasion. We have also benefited from comments from George Alessandria, Costas Arkolakis, Ariel Burstein, Jonathan Eaton, Oleg Itskhoki, Sam Kortum, Andrei Levchenko, Eduardo Morales, Ezra Oberfield, and Andrès Rodríguez-Clare, as well as seminar participants at various conferences and institutions. Xiao Ma provided outstanding research assistance. The statistical analysis of firm-level data on US multinational companies was conducted at the Bureau of Economic Analysis, US Department of Commerce, under arrangements that maintain legal confidentiality requirements. The views expressed are those of the authors and do not reflect official positions of the US Department of Commerce.

1 Introduction

Many important questions in international economics involve the complex activities of multinational enterprises (MNEs) in time and space. Consider the recent rise in protectionism worldwide: understanding how it will affect the global allocation of production in the years to come requires an understanding of the dynamics of MNEs. The recent debate about the United Kingdom abandoning the European Union, "Brexit", is one example. If Brexit happened, would MNEs pull out of the United Kingdom and reallocate toward other countries? How would trade flows linked to MNEs be affected? Would MNEs located in the EU be affected? Studying the expansion patterns of MNEs and understanding the nature of their costs are key to providing sound answers to these questions.

Despite its importance, the behavior of MNEs and their affiliates in *time and space* has received little attention in the literature. On the empirical side, this is primarily due to data limitations. On the theoretical side, the nature of the costs of MNE activity –whether variable, fixed, or sunk, and whether host- or destination-country specific– poses challenges to tractability, particularly in a multi-country dynamic setting in which MNEs can separate production locations from the destination of their sales.[1] This paper contributes to filling the gap by introducing a new multi-country dynamic model of the MNE which is informed by a new set of facts on the behavior of MNE affiliates. The calibrated model is aimed at answering counterfactual questions about the effects of MNE behavior in time and space.

Our analysis uses a long panel of US MNEs and their foreign affiliates, from the Bureau of Economic Analysis (BEA). Studying the behavior of US MNEs and their affiliates is a relevant setup because not only the United States is the main source of MNEs in the world, but also MNE affiliates are the main channel through which US firms reach foreign consumers. In 2009, for instance, majority-owned affiliates of US MNEs abroad accounted for 75 percent of US sales to foreign customers; forty percent of those affiliates' sales were exports, i.e., sales to customers outside the affiliate's host market.

We start by documenting three facts about the dynamic behavior of US MNEs and their affiliates. First, MNE expansion happens mainly at the extensive, rather than intensive, margin. We observe MNEs that expand by entering new markets, either with a new affiliate or exporting from an existing one. We do not observe intensive margin growth within a country: the ratio of affiliate-to-parent sales is flat over the affiliate's life. Second, the activities of MNE affiliates persist over the affiliate's life. At birth, most affiliates serve only their host market, and only later in life they start also

[1] See Antrás and Yeaple (2014) for a detailed survey of the main facts and theories about MNEs.

exporting to third countries. Third, the location of a new MNE affiliate does not depend on the location of preexisting affiliates—in other words, the pattern of affiliates' opening does not display "extended gravity", in contrast with the facts that Morales et al. (2015) document for exporters.

Informed by these facts, we build a multi-country dynamic model of MNE expansion. Home-based firms decide whether, when, and where to open foreign affiliates. Affiliates, in turn, can sell both to their host market and to any other market. Affiliate operations, both in the host and in the export markets, are subject to sunk, fixed, and variable costs. The MNE's decisions of whether to set up an affiliate in a market, and eventually export from it, are shaped by the interaction of firm-specific characteristics, persistent aggregate productivity and demand shocks, and the array of MNE costs.

We make two key assumptions. First, guided by the observation that almost all affiliates in the data have some horizontal sales at birth, we assume that firms that decide to do Foreign Direct Investment (FDI) must first set up an affiliate and sell to the local market, and only then they can consider exporting from that affiliate. Since the model is set up in continuous time, the decisions of opening an affiliate and exporting from it can be made virtually simultaneously, generating affiliates with exclusively horizontal sales and affiliates with both horizontal and export sales at birth, as in the data. Second, consistent with the lack of extended gravity in the data, we assume that the decision of opening an affiliate —and eventually exporting from it— is independent across markets. For instance, a firm's decision of opening an affiliate in Germany and exporting to France from it is independent of having an affiliate in France. We introduce interdependence in location choices across countries into the model by allowing the decision to open an affiliate in a country to depend on the set of countries where the affiliate can export to. In this way, the problem of the MNE takes the form of a *compound option*: opening an affiliate in a country is an option which, when exercised, gives access to a set of additional options, such as exporting from the affiliate to any other location.

Our two assumptions, together with the compound option structure, lend tractability to the model and allow us to preserve the rich heterogeneity necessary for quantitative analysis. Separating the decisions about performing affiliate activities in different countries significantly simplifies the dynamic problem of the firm. Because of the continuous time specification, value functions can be solved in closed form (up to constants) as simple additive functions of the firm's realized profit flow plus the option values of further expansion and of exit. The independence assumption together with the compound option structure imply dynamic interdependence, but static independence, of location decisions. These features avoid the permutational problem present in (static) models of export platforms, which would be extremely hard to solve in a multi-country dynamic setup.

Because of the of the firm's problem, we are able to aggregate individual firms' outcomes and to solve for the evolution of price indexes in the model. In this way, we can construct a measure of the welfare changes induced by changes in MNEs' activities.

While the static components of our model are standard and follow Melitz (2003), the way we formulate the dynamic problem is new to the international trade literature. We build on insights from the literature on real options to solve general models of investment under uncertainty (see Dixit and Pindyck, 1994). The application to the complex decisions of the MNE appears natural, since MNE location and export decisions happen over time, and they are likely to be affected by uncertainty in demand and other market characteristics.[2]

We calibrate the model to match static and dynamic moments for US MNE affiliates located in the top ten host countries for US FDI, over thirty years. Our calibration implies that opening and operating affiliates is more costly than exporting from them, for most host countries. Finally, export sales to the United States (the Home country) are generally associated with lower barriers than sales to other export destinations. Heterogeneity, however, is large across host countries, sales types, and friction types.

The calibrated model is able to reproduce non targeted observations from the data related to the selection patterns of MNE affiliates within and across host markets. A size advantage in terms of horizontal sales is observed for: affiliates that export over affiliates that do not exports; affiliates that export earlier in their life over affiliates that export later ; and affiliates that are first within the MNE over subsequent affiliates. Moreover, on average, the first affiliate of an MNE is established in a host market that is easier to access relative to the host markets of subsequent affiliates.

Armed with the calibrated model, we perform various counterfactuals to evaluate the importance of different frictions to MNE expansion, of the resulting endogenous price index adjustments, and of the compound option structure. Since our sample includes affiliates located in the United Kingdom, Ireland, Germany, and France, we use the potential withdrawal of the United Kingdom from the European Union (EU), Brexit, as our main counterfactual exercise.

Different potential implementations of Brexit are related to increasing different types export costs between the United Kingdom and the EU. Our model predicts that the increase in export costs between the United Kingdom and other EU countries would have a static effect, a dynamic effect, and an equilibrium price effect. First, export activities between the United Kingdom and the EU

[2] The compound option formulation can be useful also to treat problems related to the MNE's global sourcing decisions, which are likely to occur over time and under uncertainty. One can imagine a set up in which making an investment to source an input from a given country opens up the possibility of sourcing other, more upstream, inputs from different locations.

become more costly, so that sales from UK-based affiliates to the EU, as well as sales from EU-based affiliates to the United Kingdom, decline. This decline drives the decrease in the incentive to open affiliates in the United Kingdom and in other EU countries, due to the smaller, and costlier, export. Second, increases in trade costs affect the affiliate export band of inaction, and hence, affiliate export entry and exit gets affected. Finally, increases in trade frictions have the effect of raising prices not only in the United Kingdom, but also in the EU, encouraging more export entry from the United Kingdom into those markets. The strength of each effect on aggregate firm dynamics varies depending on the nature of the shock to export costs. For instance, while increasing sunk export costs would increase both the sales and number of affiliates selling to the EU from the United Kingdom, increases in iceberg trade costs would drastically decrease both the number and sales of UK-based US affiliates to the EU.

We relate to the existing literature in several ways. First, most contributions in the literature have analyzed MNE expansion in space, but not in time. As evident in the static models in Tintelnot (2017), Fan (2017), Arkolakis et al. (2018), and Head and Mayer (2018), allowing firms to set up affiliates in countries which differ from the destinations of their sales can result in a complex problem when fixed costs of production are taken into account. The sharp patterns that we document from observing affiliates over time help to simplify this problem by reducing the choice set of firms in a way that is consistent with the data.

Second, there is a small, but growing, literature that analyzes different aspects of the dynamic behavior of the MNE. Papers in this literature limit, however, the spatial dimension of the problem. In a model with firm-level shocks, Gumpert et al. (2018) focus on the life-cycle dynamics of the proximity-concentration tradeoff—i.e., sales of MNE affiliates are only horizontal and an alternative to exports from the Home market—and assess the role of MNEs on new exporters' dynamics, using rich firm-level data from various countries. Given the nature of their question, the analysis does not consider export platforms (nor endogenous adjustments in prices), and focuses on the affiliates' life-cycle, rather than aggregate, dynamics. Fillat and Garetto (2015) build a dynamic two-country model of the proximity-concentration tradeoff with aggregate shocks. Importantly, they introduce the idea that MNE activities can be treated as a real option that gets exercised once an affiliate is opened abroad.[3] Fillat et al. (2015) extend this idea to a multi-country setup. Both papers focus on the link between the MNEs' expansion decisions and asset prices, and both assume that the activities of affiliates are restricted to the market of operation.[4] Our model treats MNE activities

[3] Impullitti et al. (2013) also use a real option to model exporters' entry and exit patterns.

[4] Additionally, Ramondo et al. (2013) study the implications of the proximity-concentration tradeoff under uncertainty and use BEA data to assess the predictions of the model. Conconi et al. (2016) couple a model of the proximity-concentration tradeoff with learning and test it using detailed data for Belgium. Focusing only on MNEs, Egger et al. (2014) propose a learning model to explain the sequential entry into markets of German MNEs. All these

as a compound, rather than a simple, option. In this way, we are able to preserve the tractability of the problem in a dynamic multi-country setup, and expand on the spatial dimension by separating activities of MNE affiliates between the locations of production and sales.

Third, our paper is naturally related to the large literature on export dynamics, which has been primarily concerned with quantifying the various costs of export activities and their welfare implications.[5] Complementing this literature, we quantify the frictions to the expansion of MNEs in time and space, and analyze the implications in terms of firms' aggregate dynamics and welfare.[6] However, an important difference with the export dynamics literature is that the nature of the MNE problem is more complex, and subject to more frictions, than the exporter problem; MNEs choose not only which markets to serve, as an exporter does, but they also choose the location from where to serve each of those markets. Our compound-option structure, together with the assumptions on the timing of MNE decisions and independence of entry decisions, allows us to solve the complex problem of the MNE in a dynamic multi-country setup.

Finally, our paper relates to the large literature that analyzes the dynamics of domestic firms, which goes back to Davis et al. (1996), and more recently Decker et al. (2014, 2015). Our facts suggest that the dynamics of MNE affiliates are starkly different from the dynamics of domestic firms. We interpret the differences between the behavior of new US firms in the domestic and foreign markets as indicative of the fact that they face very different sets of frictions.

2 Establishing the Facts

We document three novel facts on the dynamic behavior of foreign affiliates of US multinational enterprises (MNEs). First, MNE expansion happens at the extensive, rather than the intensive, margin. Second, the vast majority of affiliates are born specialized in sales to the host market. This activity remains the main activity of the affiliate, while export activities may start later in life. Finally, the location of new affiliates does not depend on the location of preexisting affiliates.

papers limit both the spatial dimension of their analysis, by considering only horizontal FDI sales, and the dynamic dimension, as they are featuring two-period models.

[5] Earlier contributions by Baldwin and Krugman (1989), Roberts and Tybout (1997), Das et al. (2007), and Alessandria and Choi (2007) find evidence of large sunk costs of exporting by focusing on observed patterns of export entry and exit. Subsequent analyses, such as Eaton et al. (2008) and Ruhl and Willis (2017), incorporate facts related to the life-cycle dynamics of new exporters and find that those costs are much lower. Alessandria et al. (2015) take a further step and also calculate the welfare gains from trade in a dynamic setting that matches well the life-cycle export facts. Arkolakis (2016) presents rich micro evidence on firm selection and export growth that supports dynamic theories of endogenous entry costs *vis-á-vis* standard export sunk costs. Finally, Fitzgerald et al. (2017), using detailed data on export prices and quantities, show that life-cycle growth of those two variables are quite different.

[6] Welfare analysis refers to changes in the price index in each country.

2.1 Data

Our empirical analysis uses the firm-level data on the operations of US MNEs, from the Bureau of Economic Analysis (BEA). The data include detailed information on the operations of MNEs in the United States and their affiliates abroad, for the period 1987-2011. We restrict the sample to majority-owned affiliates that do not operate in tax haven countries, have manufacturing as their primary activity, and belong to a US parent operating in any sector.[7] We further consolidate affiliates belonging to the same parent and operating in the same country and 3-digit industry. Finally, for the facts presented in this section, we focus on affiliates that open during our sample period and that survive for at least ten consecutive years in the market. This restriction implies that we exclude affiliates that open in 2003 or later, as well as observations for affiliates in their eleventh year of life, or greater. We also remove affiliates and parents with zero total sales.[8]

Crucially, the BEA data break down affiliate sales by destination: the host market of operation (horizontal sales), and other markets (exports). The data further distinguish between exports to the United States and to third markets, and data in survey benchmark years further distinguish affiliate exports to Canada, the United Kingdom, and Japan.[9]

Table 1 shows the number of observations with positive horizontal and export sales in our sample. Almost 95 percent of our affiliate-year observations have some horizontal sales, while more than two thirds of them have some exports. More than one third of the observations correspond to affiliates with horizontal sales only, while the share of affiliates with only exports is around six percent. Since affiliates that only export are few and account for a small share of total affiliate sales, the model we present in Section 3 does not generate pure exporters.

Appendix A provides more details on the data coverage and sample construction.

2.2 The expansion of MNE affiliates

We start by documenting that MNE affiliates grow by entering new destination markets.

[7] Our sample is primarily composed of affiliates that are majority owned during their whole life. Only about one percent of affiliates go from majority to minority owned and less than two percent go from minority to majority owned.

[8] This restricted sample covers 23 percent of all new affiliates in manufacturing as well as 38 percent of their total sales. Facts computed using a larger sample with a five-year survival threshold display the same patterns (not shown).

[9] The distinction between the United States and other affiliate export markets does not make any substantial difference for the facts documented below. We do, however, use the available country-specific affiliate export data in our calibration. It is also important to notice that the BEA data do not provide information about parents' direct exports by destination.

Table 1: Number of observations, by sale type.

	Horizontal sales	Export sales
No. of observations	38,080	38,080
with positive sales	36,135	25,958
	(95%)	(68%)
of pure type	14,035	2,418
	(37%)	(6.3%)
Sales accounted by pure type	15.6%	7.7%

Note: Observations are at the affiliate-year level, for new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. A pure-type affiliate is an affiliate for which at least 99 percent of sales are either only horizontal or only export sales.

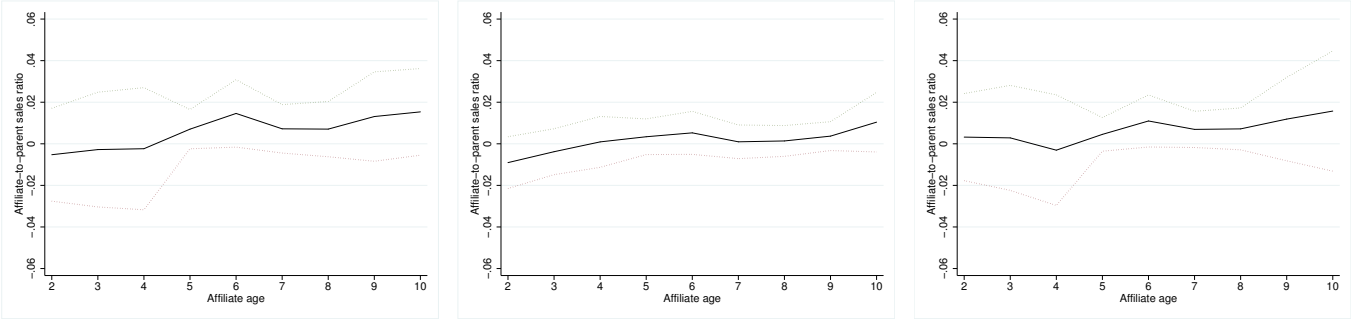

Figure 1 shows the ratio of affiliate-to-parent sales, by affiliate age, for all, horizontal, and export sales, respectively. We plot the coefficients on age dummies from estimating, by Ordinary Least Squares (OLS),

$$\log Y_{iap} = \sum_{a=2}^{10} D_{iap} + \beta_1 \log \text{affiliate emp}_{iap} + \beta_2 \log \text{global emp}_{iap} + u_{iap}. \tag{1}$$

The dependent variable Y_{iap} denotes the ratio of affiliate-to-parent sales for affiliate i belonging to parent p at age a, while D_{iap} is an age dummy. We also control for the affiliate's employment and the global employment of the MNE.We include country-year and affiliate fixed effects.

Figure 1: Affiliate-to-parent sales ratio, intensive margin.

(a) All sales (b) Horizontal sales (c) Export sales

Notes: OLS coefficients on age dummies (relative to the entry year) from estimating (1), with affiliate fixed effects and country-year fixed effects. Five-percent confidence intervals are shown with dashed lines. Sample of new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. Each panel includes affiliates with positive sales in the given category.

The affiliate-to-parent sales ratio is flat: at all ages, this ratio is not significantly different from the

ratio in the entry year. A similar lack of growth is observed not only for all affiliate sales, but also for horizontal and export sales, separately. Moreover, the lack of growth is not only observed within affiliates, but also across affiliates of different ages, as shown in Appendix Figure B.1 including industry fixed effects.

MNE affiliates do not grow at the intensive margin, but they do expand at the extensive margin, i.e., adding destinations other than the host market. Table 2 shows the results from estimating, by OLS,

$$\log Y_{iap} = \sum_{\delta \in \{-5,1\} \cup \{1,5\}} D_{i\delta p} + \beta_1 \log \text{affiliate emp}_{iap} + \beta_2 \log \text{global emp}_{iap} + u_{iap}, \qquad (2)$$

where $D_{i\delta p}$ equals one when affiliate i is δ years away from starting exporting. We also control for the affiliate's employment and the global employment of the MNE. We include country-year and affiliate fixed effects.

Results in Table 2 are relative to sales in the entry year into exports, the excluded category. In each of the five years preceding export entry (-5- to -1), the ratio of affiliate-to-parent sales is significantly lower than the ratio at entry. After export entry (1 to 5), this ratio is flat. The similarity of the coefficients for $\delta = \{-5, \ldots, -1\}$ indicates that the affiliate-to-parent sales ratio increases only at the time of export entry. Expansion happens only at the extensive margin of sales destinations.

Robustness. One could argue that the lack of growth in MNE affiliates' sales may be due to the fact that the affiliate "inherits" the age of the parent so that, *de facto*, it is a much older firm, and hence, has lower growth rates. This may well be happening, as documented for multi- versus single-plant firms in the United States by Kueng et al. (2016).[10] Unfortunately, the BEA data do not record the age of the parent firm. However, we can look at the affiliate position in the opening sequence of the MNE—i.e., first affiliates versus subsequent affiliates. In this way, we can compare affiliates belonging to younger MNEs with affiliates belonging to older MNEs (or to the same MNE at older ages). Columns 1-4 in Appendix Table B.1 show that first affiliates do not appear to grow faster than subsequent affiliates.

A second argument can be that, since global value chains (GVCs) have been growing very fast in the last decades, affiliates linked to them might be the ones also growing faster. In columns 5-8 in Appendix Table B.1, we show the results of estimating (1) separately for GVC affiliates (defined as affiliates with positive intra-firm exports, imports, or both), and for non-GVC affiliates (defined as

[10] Kueng et al. (2016) document a stark difference in the life-cycle employment profiles of establishments belonging to single- versus multi-unit firms in manufacturing: while establishments in single-unit firms grow steeply, the ones in multi-unit firms do not grow.

Note: Results from estimating (2) by OLS. Observations at the affiliate-year level, for new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. The dependent variable *affiliate to parent sales* refers to affiliate sales relative to the domestic sales of the US parent. We run this specification including only affiliates that start exporting during our sample period. All specifications include affiliate and country-year fixed effects. Standard errors, clustered at the parent level, are in parenthesis. Levels of significance are denoted $^{***}p < 0.01$, $^{**}p < 0.05$, and $^{*}p < 0.1$.

affiliates with zero intra-firm exports and imports). Both groups have flat affiliate-to-parent sales ratios.

A third argument for the observed lack of growth in MNE affiliates' sales is related to the mode of FDI entry. If MNEs establish foreign affiliates mostly through a merger with—or an acquisition of—an existing firm (M&A), one could argue that "new" foreign affiliates are in reality preexisting firms that likely grew before their acquisition. The BEA asks to a subset of affiliates whether they were created through an M&A or a greenfield project.[11] Columns 9-12 in Appendix Table B.1 show that, relative to age two (the first year for which sales are recorded for the whole year), the sales ratio is flat, regardless of the mode of FDI entry.

A final concern is that the flat sales ratio observed for affiliates may be due to the fact that firms grow in a foreign market first through exports, and only subsequently through opening an affiliate. Since the BEA data do not include information about parent exports by destination market, unfortunately, this analysis is not feasible. Gumpert et al. (2018), however, report that — for Norway and France— the difference in growth profiles for MNEs with previous export experience into a market and those without it is not significant, except for the first year of the affiliate's life.

The fact presented in this section motivates an important feature of the model we present below, namely that MNEs grow at the extensive margin of destination countries only.

2.3 The activities of MNE affiliates over time

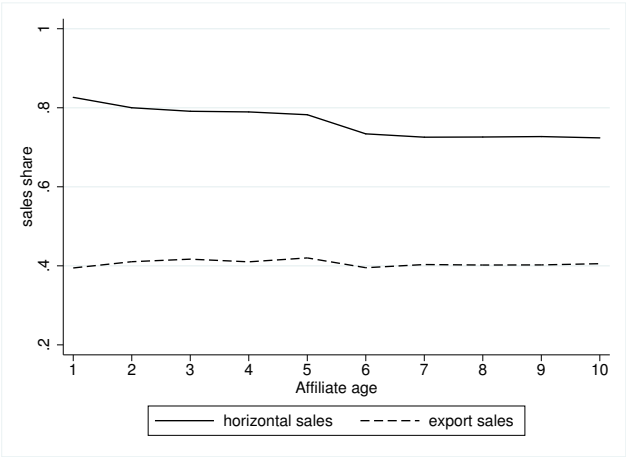

We now present evidence on the specialization patterns of affiliates in terms of horizontal and export activities over time. We show that affiliates are born specialized in horizontal sales, and eventually they incorporate exports as a secondary activity later in life.

Figure 2 shows the evolution of the intensive and extensive margins of horizontal and export sales, respectively, as shares of total sales of the affiliate. Figure 2a shows the evolution of the horizontal and export sales share, computed as an average over affiliates reporting, respectively, positive horizontal and positive export sales. On average, horizontal sales account for about 80 percent of affiliate sales at birth and decrease by ten percentage points over the first ten years of life of the affiliate, while the export share is flat at 40 percent. To capture the extensive margin of horizontal and export sales, Figure 2b plots the percentage of affiliates with non-zero horizontal sales and non-zero export sales, respectively. While the share of affiliates with horizontal sales is stable at more than 95 percent, the share of exporting affiliates increases from 50 to 70 percent during the

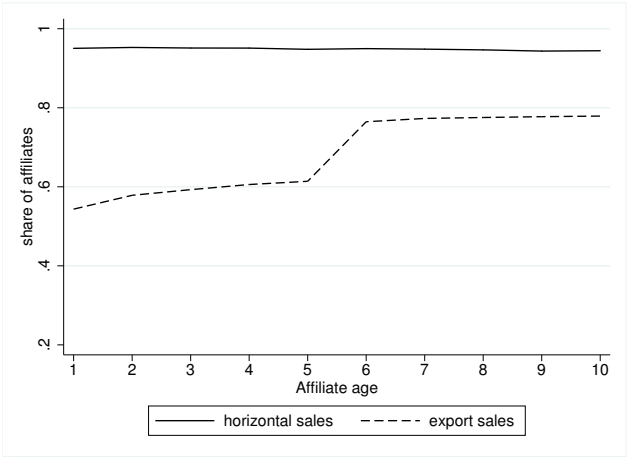

[11] This question applies only to firms that opened mid-year, and thus, the reported information about sales covers only part of the entry year. For this reason, we compute the ratio of affiliate-to-parent sales starting at age two.

Figure 2: Intensive and extensive margins of affiliate sales, by type.

(a) Affiliate sales shares

(b) Share of affiliates

Notes: Sample of new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. Horizontal and export sales refer, respectively, to sales to the market where the affiliate is located, and to sales to markets outside the local market. (2a): average sales, as a share of total affiliate sales, include affiliates with positive horizontal and export sales, respectively. (2b): number of affiliates, as a share of the total number of affiliates, include affiliates with positive horizontal and export sales, respectively.

first ten years of life of the affiliate. In other words, for horizontal activities, changes in sales shares are due to the intensive margin, while export shares increase only because of affiliates which start exporting. Hence, the data suggest that, over time, affiliates incorporate export sales into their activities, but they never stop selling in their host market.

The patterns in Figure 2 are confirmed by OLS regressions that include a battery of fixed effects, as shown in Appendix Table B.2. Estimates that include affiliate fixed effects suggest that, on average, horizontal (export) sales shares decrease (increase) during the life of an affiliate, and the share of affiliates with exports is higher among older affiliates.

For robustness, the appendix reports analogous results (Appendix Figure B.2 and Table B.3) for the subset of affiliates that are pure type at birth—i.e., firms that in their first year of life either sell exclusively to the host market or only export. The results on pure-type affiliates reinforce the patterns shown in Figure 2: pure-type affiliates diversify their activities over the life-cycle, moving from exclusively horizontal affiliates to export activities at some point in their life. Relatedly, Appendix Figure B.3 shows a more general relation between the intensity at which an activity is performed and the time at which the affiliate first starts such activity: the older the affiliate is when it starts a new activity (e.g., export sales), the lower the intensity at which that activity is performed.

The fact documented in Figure 2 motivates an important assumption of our model: all affiliates start operations with some horizontal sales and may endogenously expand into export markets.

2.4 Geography and the entry pattern of MNE affiliates

We now present a fact related to the sequence of location decisions of the MNE.In particular, we document the lack of "extended gravity": the location of a new affiliate does not depend on the location of preexisting affiliates, either in terms of geographic distance or of other measures of similarity between markets.

Table 3 shows that, for a given US parent, the unconditional probability of opening an affiliate in a country is very similar to—and in several cases statistically insignificant from—the probability of opening an affiliate conditional on already having an affiliate in a "similar" country. Following Morales et al. (2015), we define "similarity" in a variety of ways: similar countries may be located in the same continent, share a border, share a language, have similar income per capita, or all of the above.[12] Of course, this comparison is only possible for US parents with at least two foreign affiliates. We further restrict the sample to affiliates located in the ten most popular host countries for US MNEs, which cover about 60 percent of all sales of majority-owned US affiliates abroad. The table shows that the largest differences in conditional and unconditional probabilities are observed for countries, such as China, that are typically part of global supply chains. Differences become smaller if we restrict the sample to MNEs with more than five, or more than ten, affiliates (see Appendix Table B.4)

Extended gravity is much less pronounced for MNEs entering markets by opening new affiliates than for exporters. Morales et al. (2015) find that the probability of exporting to a given country is 12.7, 5.3, 3.0, and 2.9 *times* higher if the firm already exports, respectively, to an adjacent country, to a country in the same continent, to a country sharing the same language, and to a similar country in terms of per capita income. In contrast, we find that the probability of opening an affiliate in the United Kingdom, for example, is 17.5, 8.7, 2.8, and 2.4 *percent* higher if the firm already has an affiliate, respectively, in an adjacent country, a country in the same continent, a country sharing the same language , and a country in the same income group.

The observed lack of extended gravity in affiliates' entry motivates a key assumption of our model: the choice of opening an affiliate in a country is independent from the location of preexisting affiliates of the same parent.

[12] We use the World Bank classification and divide countries into four groups according to their GDP per capita. We refer to two countries belonging to the same income group as similar in terms of income per capita.

Table 3: Unconditional and conditional probability of affiliate entry.

Note: Probabilities of affiliates' entry into the top-ten most popular destinations of US MNEs. Conditional probabilities refer to the probability of observing a MNE opening an affiliate in country i given that the parent already has an affiliate in a "similar" country. Column 6 refers to similarity in all the dimensions in columns 2-5. The sample is restricted to parents with at least two affiliates worldwide. P-values from tests of equality of the conditional and unconditional probabilities are in parentheses. Conditional probabilities in ***bold*** are not significantly different from the relevant unconditional probability.

Relatedly, at the affiliate-export level, we find suggestive evidence that an affiliate's decision to enter an export market is independent from whether its parent already has an affiliate in that country. With the BEA data, we are able to examine the coexistence of affiliates' exports to three countries (Canada, the United Kingdom, and Japan) with the presence of affiliates owned by the same parents in those countries, for the benchmark year 2004. Of the 20,359 affiliates that export to Canada, 64 percent belong to a US parent that also has affiliates located in Canada. Similarly, of the 5,017 affiliates that export to the United Kingdom, 70 percent belong to a US parent that also has affiliates located in that country. Finally, of the 5,224 affiliates that export to Japan, 47 percent belong to a US parent that also has affiliates located in Japan.

This finding motivates an independence assumption on export entry: an affiliate's decision to export to a destination does not depend on the location of other affiliates of the same parent.

3 A Dynamic Model of MNE Expansion

We build a quantitative dynamic model where MNEs open affiliates across countries over time. Affiliates sell in their host markets (horizontal sales), and they choose whether to export to other markets from there. We impose assumptions that are guided by the facts documented in Section 2 and are key for the tractability of the model.

While the static components of our model are standard and follow Melitz (2003), the dynamic part of the model is based on a compound option formulation that allows us to capture the richness of the decisions of the MNE in time and space. This formulation is novel to the international trade literature, and it is the key element that makes the model amenable to quantitative analysis.

3.1 Preferences and technology

The economy consists of $N+1$ countries: the Home country (the United States in our data) and N foreign countries. Time is continuous. In each country k, consumers have preferences over a composite good,

$$U_k = \int_0^\infty e^{-\rho t} Q_k(t) dt, \tag{3}$$

with ρ denoting the subjective time discount rate. The quantity $Q_k(t)$ aggregates a continuum of varieties, indexed by v, with a constant elasticity of substitution (CES) $\eta > 1$,

$$Q_k(t) = \left[\sum_i \sum_j \int_{\Omega_{ijk}(t)} \lambda_{ijk}^{\frac{1}{\eta}} q_{ijk}(v,t)^{\frac{\eta-1}{\eta}} dv \right]^{\frac{\eta}{\eta-1}}. \quad (4)$$

The quantity $q_{ijk}(v,t)$ denotes consumption of variety $v \in \Omega_{ijk}(t)$, and $\Omega_{ijk}(t)$ denotes the set of varieties sold to country k and produced by affiliates located in j belonging to firms from i, at time t. The term λ_{ijk} denotes a preference shifter.

Assumption 1. *Varieties consumed and produced are origin-location-destination specific.*

Assumption 1 implies that consumers perceive differently varieties produced in different locations by the same firm. For example, consumers in a given destination perceive Möet Chandon champagne produced in France as different from Chandon sparkling wine produced by the same firm in California. Importantly, this assumption implies that there is no cannibalization of sales when a MNE enters a country by opening an affiliate *and* also exporting there from an affiliate in a different location.

Each country is populated by a continuum of firms. The Home country is the only source of MNEs: Home firms decide whether to operate only in their home market or to also establish affiliates abroad. For this reason, to simplify notation, we remove the index i that denotes a variety's origin country and use the subscript d to refer to the parent's operations at Home.

Labor is the only factor of production. Each firm produces with a linear technology and operates under monopolistic competition. As in Melitz (2003), each firm is characterized by a productivity parameter φ that determines the unit labor cost of the good it produces. Each firm sets prices to maximize profits from sales to each destination, $p_{jk}(\varphi) = \widetilde{\eta} c_{jk}(\varphi)$, with $\widetilde{\eta} \equiv \eta/(\eta-1)$ and $c_{jk}(\varphi) \equiv w_j \tau_{jk}/\varphi$. The term w_j denotes the wage in the country j where production takes place, and τ_{jk} denotes the iceberg trade cost to ship goods from production location j to destination k, with $\tau_{jk} \geq 1$, $\forall j \neq k$, and $\tau_{jj} = 1$.

A firm's domestic profits are then given by $\pi_d(\varphi) = H(w_d/\varphi)^{1-\eta} P_d^{\eta} \lambda_d Q_d$, and the variable profits from sales to k of an affiliate in j are given by $\pi_{jk}(\varphi) = H(\tau_{jk} w_j/\varphi)^{1-\eta} P_{jk}^{\eta} \lambda_{jk} Q_{jk}$, where $H \equiv \eta^{-\eta}(\eta-1)^{\eta-1}$. The variable Q_{jk} denotes the aggregate quantity demanded in k of goods produced by affiliates of US MNEs in j, $Q_{jk} = \left[\int_{\Omega_{jk}} q_{jk}(v)^{\frac{\eta-1}{\eta}} dv\right]^{\frac{\eta}{\eta-1}}$, and P_{jk} is the corresponding CES price sub-index. Note that, for $j = k$, the variable π_{jk} denotes profits from horizontal sales, while for $j \neq k$ it denotes profits from affiliate export sales.

When a firm establishes an affiliate in a foreign country j, it has to pay a sunk entry cost, $F_j^h > 0$. The affiliate starts by selling locally and incurs a per-period fixed cost, $f_j^h > 0$. Once the affiliate is in place, it can expand its operations to export to other markets. An affiliate located in country j has to pay a sunk entry cost $F_{jk}^e > 0$ to start exporting to country k, and a per-period fixed export cost $f_{jk}^e > 0$. For simplicity, we assume that there are no per-period fixed costs associated with domestic production, so that all firms produce at Home.

3.2 The MNE dynamic problem: the compound option

We now present the MNE dynamic problem. At each point in time, a firm endogenously decides whether to open an affiliate in a foreign country, and whether and where to export from its existing affiliates, including exporting to the Home market. A firm may also decide to shut down affiliates or to exit any of its affiliate export markets.

We use the notion of a *compound option* to model the dynamic problem of the MNE. Opening an affiliate in a country is an option that, when exercised, gives access to another set of options, namely the possibility of expanding to each export destination. Hence, the decision to open an affiliate in country j depends on the set of countries where the affiliate can export to. The compound-option structure allows us to easily solve backwards the firm's problem, as suggested by Dixit and Pindyck (1994, chap. 10). Conditional on the MNE having an affiliate in country j, one can solve for the value of exports to each destination, and for the policy functions that induce the affiliate to start or stop exporting to each country $k \neq j$. Together with the value of horizontal sales, this determines the value of an affiliate in country j. Then, one can solve for the policy functions that induce the firm to open, or shut down, that affiliate.

The two assumptions we present next, together with the compound option formulation, make the model tractable and allow us to make headway toward a rich quantitative analysis. Both assumptions are guided by the empirical observations in Section 2.

Assumption 2. *The decision to open an affiliate in a country, and export from there, is independent from the decision to open affiliates in any other country.*

This assumption is equivalent to imposing that the profits of an affiliate in a country are independent from the number of affiliates that the firm has. Together with Assumption 1, it implies that the same firm can serve a market through affiliates operating there and through exports from affiliates located elsewhere.

Assumption 3. *A new affiliate sells in the host market before it eventually starts to export.*

Assuming sequential decisions is a mere artifact to gain tractability: because the model is specified in continuous time, opening an affiliate and exporting from it can happen almost simultaneously, allowing for affiliates to export from birth.

Shock structure. Following Ghironi and Melitz (2005), we define the firm-level productivity φ to be the product of a time-invariant firm-specific component, z, and of a time-varying Home country-specific component, Z, so that $\varphi \equiv z \cdot Z$. The term z is a firm-specific draw from a distribution $G(z)$ which is constant over time, as in Melitz (2003). We assume that $Z = e^X$, where X is a Brownian motion with drift,

$$dX = \mu dt + \sigma dW, \tag{5}$$

for $\mu \in \Re$ and $\sigma > 0$, and dW denoting a standard Wiener process. This specification is equivalent to assuming that aggregate Home productivity behaves like a random walk, and that productivity growth is independently and identically distributed. This is a convenient functional form assumption, which guarantees the tractability of the model's solution.

We assume that when a firm operates an affiliate in a foreign country, it transfers both the aggregate and the idiosyncratic components of the productivity shock to the host market, so that MNEs operations contribute to the transmission of productivity shocks across countries, in the spirit of Cravino and Levchenko (2017).

We also introduce host-country aggregate demand shocks by assuming that aggregate demand in destination country k evolves according to a geometric Brownian motion,

$$dQ_k = \mu_k Q_k dt + \sigma_k Q_k dW_k, \tag{6}$$

where $\mu_k \in \Re$, $\sigma_k > 0$, and dW_k denotes a standard Wiener process, possibly correlated with the Home aggregate productivity shock.

Affiliate profits from sales to country k are linear in the term $e^{(\eta-1)X}Q_k$. Thus, it is convenient to define the "composite" shock $Y_k \equiv e^{(\eta-1)X}Q_k$, which captures the effect of both source- and destination-country aggregate shocks on affiliates' profits. The shock Y_k is also a geometric Brownian motion with drift $\tilde{\mu}_k$ and variance $\tilde{\sigma}_k^2$ given, respectively, by

$$\tilde{\mu}_k = \mu_k + \mu(\eta-1) + \frac{\sigma^2}{2}(\eta-1)^2 + \gamma_k \sigma_k \sigma, \tag{7}$$

$$\tilde{\sigma}_k^2 = \sigma_k^2 + \sigma^2(\eta-1)^2 + 2\gamma_k(\eta-1)\sigma\sigma_k, \tag{8}$$

where γ_k denotes the correlation between e^X and Q_k.

We show below that the model can be solved in terms of realizations of the composite shock. Together with the independence assumption, this shock structure ensures that only Home- and destination-country shocks are important for the dynamic decision of a firm to serve a market.

The shock structure we feed into the model is driven by both observations in the data and analytical convenience. Empirically, Appendix Table B.5 shows that most of the variation in MNE affiliates' sales is explained by country-specific time-varying shocks and parent fixed effects, rather than parent- and affiliate-level time-varying shocks. In the calibration, the introduction of country-specific demand shocks allows us to match the evolution of affiliate presence in different host countries. Computationally, relying only on aggregate shocks makes feasible the aggregation of individual firms' decisions and the computation of equilibrium price indexes in many countries.[13]

Finally, the assumption that the MNE transfers its productivity to the affiliates abroad, together with the presence of country-level shocks, implies that, conditional on entry, a firm's Home and foreign sales perfectly co-move, as it appears to be the case in the data (see Figure 1). The specification of the aggregate shock as a unit root process drives persistence in the affiliate's activities. Together with aggregate productivity growing over time ($\mu \geq 0$), this persistence gives rise to the affiliate dynamics pattern documented in Figure 2: affiliates start serving their host market, and later on, they start expanding internationally. The inclusion of iceberg trade costs further implies that export activities are performed at lower intensity.

Bellman equations. The state of the economy is described by the $(N+1)$-tuple $(X, \mathbf{Q})$, where $\mathbf{Q} = [Q_1, \ldots, Q_N]$. Let $\mathcal{V}(z, X, \mathbf{Q})$ denote the expected net present value of a Home country firm with productivity z that follows an optimal policy when the state of the economy is $(X, \mathbf{Q})$. Thanks to the independence assumption, we can write such value as

$$\mathcal{V}(z, X, \mathbf{Q}) = V_d(z, X) + \sum_{j=1}^{N} \max\left\{V_j^o(z, X, \mathbf{Q}), V_j^a(z, X, \mathbf{Q})\right\}. \tag{9}$$

The function $V_d(z, X)$ is the value of domestic sales, $V_j^o(z, X, \mathbf{Q})$ is the option value of opening an affiliate in country j, and $V_j^a(z, X, \mathbf{Q})$ is the value of an affiliate in country j, regardless of the destination of its sales. In turn, the value of an affiliate in country j is given by

$$V_j^a(z, X, \mathbf{Q}) = V_j^h(z, X, \mathbf{Q}) + \sum_{k \neq j} \max\left\{V_{jk}^o(z, X, \mathbf{Q}), V_{jk}^e(z, X, \mathbf{Q})\right\}. \tag{10}$$

$V_j^h(z, X, \mathbf{Q})$ is the value of horizontal sales in country j, $V_{jk}^o(z, X, \mathbf{Q})$ is the option value of exporting

[13] By relying on aggregate shocks only, we don't need to keep track of changes in the firms' productivity distribution over time, significantly limiting the dimensionality of the state space.

to country k for an affiliate located in j, and $V^e_{jk}(z, X, \mathbf{Q})$ is the value of exports to country k for an affiliate located in j. In this way, the problem is formulated as a compound option because opening an affiliate in a country is equivalent to exercising an option that gives access to another set of options: the options to export to any other country.

Since all firms operate in the domestic market, the value of domestic operations is simply given by the evolution of domestic profits over time, and depends only on the domestic shock X. Over a generic time interval Δt, the value of domestic operations is

$$V_d(z, X) = \frac{1}{1 + \rho \Delta t} \left[\pi_d(z, X) \Delta t + E[V_d(z, X')|X] \right], \tag{11}$$

where X' denotes the realization of aggregate Home productivity next period.

If a domestic firm does not yet have an affiliate in country j, all the value from its potential operations in j is option value—i.e., the value of the possibility of entering j in the future,

$$V^o_j(z, X, \mathbf{Q}) = \max \left\{ \frac{1}{1 + \rho \Delta t} E[V^o_j(z, X', \mathbf{Q}')|(X, \mathbf{Q})]; V^a_j(z, X, \mathbf{Q}) - F^h_j \right\}, \tag{12}$$

where $\mathbf{Q}'$ denotes the vector of realizations of demand shocks next period. This equation describes the fact that a firm may keep the option of entering market j, or may enter country j by opening an affiliate there, in which case it pays the entry cost F^h_j and gets the value of an affiliate in country j, $V^a_j(z, X, \mathbf{Q})$.

Since we assume that all affiliates sell in the market where they are located, the value of horizontal sales for an affiliate in country j is given by

$$V^h_j(z, X, \mathbf{Q}) = \max \left\{ \frac{1}{1 + \rho \Delta t} \left[(\pi_{jj}(z, X, \mathbf{Q}) - f^h_j) \Delta t + E[V^h_j(z, X', \mathbf{Q}')|X, \mathbf{Q}] \right]; V^o_j(z, X, \mathbf{Q}) \right\}. \tag{13}$$

This equation captures the fact that the affiliate may survive and make profits from horizontal sales in j, or may shut down, in which case the firm gets the value of the option of opening an affiliate in j, $V^o_j(z, X, \mathbf{Q})$.

As indicated in (10), the value of an affiliate is given by the value of its horizontal sales plus the value of its export sales. The Bellman equation describing the value of the option to export to country k for a firm with an affiliate in country j is given by

$$V^o_{jk}(z, X, \mathbf{Q}) = \max \left\{ \frac{1}{1 + \rho \Delta t} E[V^o_{jk}(z, X', \mathbf{Q}')|(X, \mathbf{Q})]; V^e_{jk}(z, X, \mathbf{Q}) - F^e_{jk} \right\}. \tag{14}$$

This equation captures the fact that the affiliate may keep the option of exporting to country k—and get the continuation value of that option—or may start exporting to country k, in which case it pays the entry cost F^e_{jk} and gets the value of exporting to k from j, $V^e_{jk}(z, X, \mathbf{Q})$, which in turn is given by

$$V^e_{jk}(z, X, \mathbf{Q}) = \max\left\{\frac{1}{1+\rho\Delta t}\left[(\pi_{jk}(z, X, \mathbf{Q}) - f^e_{jk})\Delta t + E[V^e_{jk}(z, X', \mathbf{Q}')|(X, \mathbf{Q})]\right]; V^o_{jk}(z, X, \mathbf{Q})\right\}. \tag{15}$$

This expression captures the fact that the affiliate may keep exporting to country k—and get the continuation value of that option—or may stop exporting to country k, in which case it gets the value of the option of exporting to k from j, $V^o_{jk}(z, X, \mathbf{Q})$.

Value functions. The problem can be solved backwards by first solving for $V^o_{jk}(z, X, \mathbf{Q})$ and $V^e_{jk}(z, X, \mathbf{Q})$, conditional on the firm having an affiliate in country j. Once the location of the affiliate is determined, the only country j-specific variables in the firm's problem are wages and iceberg costs, which are time invariant. For this reason, thanks to the independence assumption, the value functions only depend on the Home productivity shock and on the demand shock in destination country k. Since these shocks enter the profit functions linearly, we can replace them with the composite shocks $Y_j \equiv e^{(\eta-1)X}Q_j$.

Solving for the value of exports conditional on affiliate location is a simple case of interlinked options (see Dixit and Pindyck 1994, ch. 7), with solution given by

$$V^o_{jk}(z, Y_k) = B^o_{jk}(z)Y_k^{\beta_k}, \tag{16}$$

$$V^e_{jk}(z, Y_k) = \frac{\pi_{jk}(z, Y_k)}{\rho - \tilde{\mu}_k} - \frac{f^e_{jk}}{\rho} + A^e_{jk}(z)Y_k^{\alpha_k}. \tag{17}$$

The variables $B^o_{jk}(z) > 0$ and $A^e_{jk}(z) > 0$ are firm-specific parameters, and $\alpha_k < 0$, $\beta_k > 1$ are the roots of $\tilde{\sigma}_k^2\xi^2/2 + \left(\tilde{\mu}_k - \tilde{\sigma}_k^2/2\right)\xi - \rho = 0$. The term $B^o_{jk}(z)Y_k^{\beta_k}$ represents the option value of exporting to country k and it is increasing in the realization of the composite shock. Similarly, $A^e_{jk}(z)Y_k^{\alpha_k}$ is the option value of quitting export market k and it is decreasing in the realization of the composite shock—i.e., the option of exiting an export market has a larger value in "bad times". For each country pair (j, k) and for each firm with productivity z, the parameters $B^o_{jk}(z) > 0$, $A^e_{jk}(z) > 0$, and the thresholds for the realizations of the composite shock that induce the affiliate to start and stop exporting—i.e., the policy functions, can be recovered from the appropriate system of value-matching and smooth-pasting conditions.

Following a similar procedure, one can show that the value of horizontal sales, conditional on having

an affiliate in country j, is given by the present discounted value of profits from horizontal sales plus the option value of shutting down the affiliate,

$$V_j^h(z, Y_j) = \frac{\pi_{jj}(z, Y_j)}{\rho - \tilde{\mu}_j} - \frac{f_j^h}{\rho} + A_j^h(z) Y_j^{\alpha_j}, \tag{18}$$

where $A_j^h(z) > 0$ is a firm-specific parameter.

As a result, the value of an affiliate in country j can be written as

$$\begin{aligned} V_j^a(z, \mathbf{Y}) &= A_j^h(z) Y_j^{\alpha_j} + \frac{\pi_{jj}(z, Y_j)}{\rho - \tilde{\mu}_j} - \frac{f_j^h}{\rho} + ... \\ &\sum_{k \in \mathcal{A}_j(z)} \left[\frac{\pi_{jk}(z, Y_k)}{\rho - \tilde{\mu}_k} - \frac{f_{jk}^e}{\rho} + A_{jk}^e(z) Y_k^{\alpha_k} \right] + ... \\ &\sum_{k \notin \mathcal{A}_j(z)} \left[B_{jk}^o(z) Y_k^{\beta_k} \right], \end{aligned} \tag{19}$$

where $\mathcal{A}_j(z)$ is the subset of countries where an affiliate of firm z located in j exports to, and $\mathbf{Y} = [Y_1, \ldots, Y_N]$. The implications of the independence assumption are clearly captured by (19): the value of an affiliate does not depend on the sales, or on the value of the firm's affiliates in other countries; it does depend, however, on the set of export destinations available from the affiliate's host country.

It remains to solve for the decision of a firm to set up an affiliate in country j. The option value of opening an affiliate in j is

$$V_j^o(z, Y_j) = B_j^o(z) Y_j^{\beta_j}. \tag{20}$$

Hence, for each host country j and for each firm with productivity z, the parameters $B_j^o(z) > 0$, $A_j^h(z) > 0$, and the thresholds of the realizations of the composite shock that induce the firm to open and shut down an affiliate can be recovered from the appropriate system of value-matching and smooth-pasting conditions.

Lastly, the value of domestic sales is simply given by the present discounted value of profits from domestic sales,

$$V_d(z, X) = \frac{\pi_d(z, X)}{\rho - \hat{\mu}}. \tag{21}$$

Details on the solution of the dynamic problem of the firm are shown in Appendix C.

3.3 Equilibrium Price Indexes.

Thanks to the tractability of our multi-country model, we are able to solve for the price index in each country. This calculation entails keeping track of the evolution of the mass of affiliates located in each host country j and serving each destination country k. Appendix C shows the price indexes and the law of motion for MNEs.

The ability to solve for equilibrium price indexes derives from the choices we made in terms of setup of the model and shock structure. Traditionally, general equilibrium models of trade dynamics feature firm-level shocks but do not feature sunk costs (see Luttmer, 2007, or Arkolakis, 2016). Existing dynamic models with sunk costs characterize the equilibrium dynamics for a single firm (like in Das et al., 2007 and Morales et al., 2015), or focus on stationary equilibria where aggregate variables don't change over time (like in Alessandria and Choi, 2007). These models are usually formulated in discrete time settings where the firm's value function itself needs to be solved numerically. Our continuous time formulation, coupled with unit root shocks, allows to solve for the value functions in closed form up to some constants. By featuring only aggregate shocks, we can easily solve for the price indexes as we don't need to keep track of the evolution of the firm's productivity distribution.

3.4 Model's implications

In this section, we derive some analytical properties of the model regarding the relation between firm-level productivity, host market characteristics, and affiliate entry and export entry thresholds. In order to show these results analytically, we assume that the fixed costs of affiliate operations are "small", so that there is no endogenous exit of affiliates, either from export markets or from their production locations. With this assumption, the option-value terms $A_h^e(z)$ and $A_{jk}^e(z)$ in (17), (18), and (19) are zero. Hence, we can obtain closed-form solutions for the affiliate entry and export entry thresholds, respectively,

$$Y_j^{OH}(z) = \left(\frac{\beta_j}{\beta_j - 1}\right) \cdot \left(\frac{f_j^h + \rho F_j^h}{\rho} - \mathbf{V}_j^E(z, \mathbf{Y}_{-j})\right) \cdot \left(\frac{\rho - \tilde{\mu}_j}{\kappa_{jj}(z)}\right), \tag{22}$$

$$Y_{jk}^{OE}(z) = \left(\frac{\beta_k}{\beta_k - 1}\right) \cdot \left(\frac{f_{jk}^e + \rho F_{jk}^e}{\rho}\right) \cdot \left(\frac{\rho - \tilde{\mu}_k}{\kappa_{jk}(z)}\right). \tag{23}$$

The term $\kappa_{jk}(z) \equiv H(\tau_{jk} w_j / z)^{1-\eta} P_{jk} \lambda_{jk}$ is a firm-specific revenue term, and $\mathbf{V}_j^E(z, \mathbf{Y}_{-j})$ denotes the total value of exporting from an affiliate in j for a firm with productivity z.[14]

Proposition 1. *For a given host-destination country pair, more productive firms have lower affiliate entry and affiliate export entry thresholds:* $\partial Y_j^{OH}(z)/\partial z \leq 0$ *and* $\partial Y_{jk}^{OE}(z)/\partial z \leq 0$.

Proof. See Appendix C.

Under the assumption that $Y_j^{OH}(z) < Y_{jk}^{OE}(z)$, $\forall k \neq j$ (the threshold for the shock realization that induces a firm to open an affiliate is lower than the one that induces the affiliate to export)—Proposition 1 implies that: 1) affiliates that are exporters from birth have larger horizontal sales than affiliates born with exclusively horizontal sales; and 2) conditional on aggregate productivity, or host country aggregate demand, increasing over time ($\tilde{\mu} \geq 0$), affiliates that start exporting later in life have lower horizontal sales than affiliates that start exporting earlier in life.

The upper panels of Figure 3 illustrate these predictions. The red and blue lines denote, respectively, the threshold for opening an affiliate in j, $Y_j^{OH}(z)$, and the threshold for starting exports from j to k, $Y_{jk}^{OE}(z)$. They are decreasing functions of the firm's productivity z, and hence, they are invertible functions. As Figure 3a indicates, suppose that the realization of the aggregate shock is Y' and we observe two firms having affiliates in the same host country j. Firm 1 with productivity z_1 has an affiliate in j with only horizontal sales, while firm 2 with productivity z_2 has an affiliate in j that also exports, so that $z_2 \geq z_j^e(Y') \geq z_1$. Since $z_2 \geq z_1$, the horizontal sales of the affiliate belonging to firm 2 must be larger than the horizontal sales of the affiliate belonging to firm 1. Now, suppose that the realization of the composite shock increases to $Y'' > Y'$. As illustrated in Figure 3b, $z_1 \geq z_j^e(Y'')$ and firm 1 will start exporting from its foreign affiliate in j. Hence, within a host country, affiliates that export earlier in life are more productive and exhibit larger horizontal sales than affiliates that start exporting later.

Proposition 2. *For a given firm with productivity* z*, the affiliate entry threshold is decreasing in the host market demand taste shifter,* $\partial Y_j^{OH}(z)/\partial \lambda_{jj} \leq 0$*, and increasing in the entry cost,* $\partial Y_j^{OH}(z)/\partial F_j^h \geq 0$.

Proof. See Appendix C.

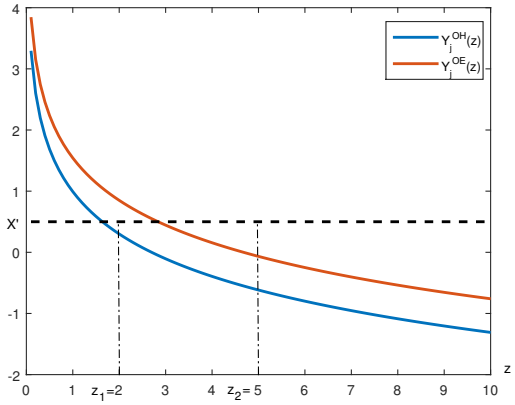

Proposition 2 relates to the expansion strategies of a MNE across countries. Since entry thresholds are decreasing in the preference shifter, the model predicts that—keeping host market size

[14] Notice that if $(f_j^h + \rho F_j^h)/\rho - \mathbf{V}_j^E(z, \mathbf{Y}_{-j}) < 0$, then $Y_j^{OH}(z) < 0$. In this case, a firm with productivity z opens an affiliate in j for any realization of Y_j because the value of its potential export network is larger than the cost of opening the affiliate. Details on the derivation of (22) and (23) are in Appendix C.

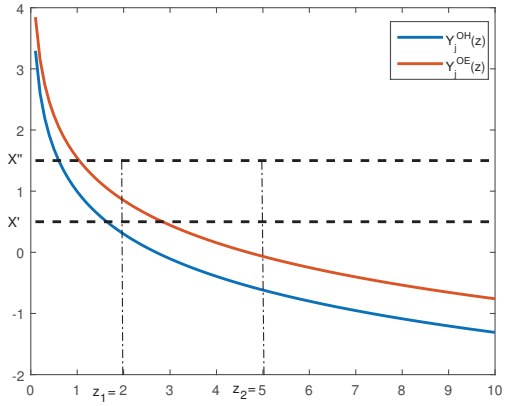

Figure 3: Model's implications.

Affiliate size, export status, and the timing of entry.

Host market characteristics and the timing of entry.

(c) Affiliate size

(d) Entry costs

constant and conditional on aggregate productivity increasing over time ($\tilde{\mu} \geq 0$)—a MNE opens first its largest affiliates and subsequently its smaller affiliates. Similarly, since entry thresholds are increasing in entry costs, the model predicts that a MNE opens first affiliates in markets that are less costly to enter. The lower panels of Figure 3 illustrate these predictions.

Figure 3c plots entry thresholds in two host countries of the same size, ($Q_k = Q_j$) but with different taste shifters ($\lambda_{kk} < \lambda_{jj}$), so that $Y_k^{OH}(z, \lambda_{kk}) \geq Y_j^{OH}(z, \lambda_{jj})$. Firm z only opens an affiliate in country j when the realization of the aggregate shock is Y'. When the realization of the shock grows to $Y'' > Y'$, the firm can afford to open an affiliate also in country k, illustrating

that, controlling for factor costs and host country size, a MNE opens first its largest affiliates. Figure 3d plots entry thresholds in two host countries with different entry costs, $F_k^h > F_j^h$, so that $Y_k^{OH}(z, F_k^h) \geq Y_j^{OH}(z, F_j^h)$. Firm z opens an affiliate in country j when the realization of the composite shock is Y'. When the realization of the composite shock increases to $Y'' > Y'$, the firm can afford to open an affiliate also in country k.

Numerical simulations of the model reveal that the implications described in this section hold also in the general case where fixed costs are sizeable and hence exit thresholds are active.

4 Calibration

We calibrate the model to match the expansion of US MNEs during the period 1987-2011 in the top-ten host countries for US FDI: Brazil, Canada, China, France, United Kingdom, Germany, Ireland, Japan, Mexico, and Singapore. We set the values of preference and technology parameters using estimates from the literature and direct observations from the data. Then, we jointly calibrate the rich set of barriers to MNE expansion included in the model to match static and dynamic moments from the BEA data.

4.1 Procedure

We set the elasticity of substitution $\eta = 5$, in line with estimates in the literature (see Broda and Weinstein, 2006). We need to set the time preference rate to $\rho = 0.1$, so that it does not violate the technical condition that ensures that the present discounted value of profits in market j does not diverge ($\rho > \tilde{\mu}_j, \ \forall j$).[15] We assume that the distribution of firm productivities is Pareto, with location parameter normalized to $b = 1$ and shape parameter $\vartheta = 4.5$, consistent with estimates in the literature (see Simonovska and Waugh, 2014).

We use data on real expenditure-based GDP growth across countries, from the Penn World Tables (9.0), to calibrate the composite shock process for each country in our sample. The composite shock Y_j captures the effect on profits of both US aggregate productivity and aggregate demand in the destination country j. We set the drift of the process, $\tilde{\mu}_j$, to match the growth rate of real GDP in country j. Matching $\tilde{\sigma}_j$ to the standard deviation of real GDP growth, however, would generate

[15] The value of $\rho = 0.1$ might appear high, but its interpretation includes economic magnitudes other than just the time preference rate. For example, if the model included an exogenous death rate, this variable would be added to the time preference rate and the technical condition would allow for a lower time preference rate. Since the solution of the model would be unchanged, we prefer not to add unnecessary parameters and rather assume a high value for the time preference rate.

too little volatility to induce reasonable firm dynamics. For this reason, we first set the standard deviation of US aggregate productivity, σ, to match the standard deviation of labor productivity among US firms, and the standard deviation of the aggregate demand shock in country j, σ_j, and its correlation with the US aggregate shock, γ_j, to match, respectively, country j's standard deviation of real GDP growth and its correlation with US GDP growth. We then use (8), together with $\eta = 5$, to recover the values for $\tilde{\sigma}_j$. To initialize the shock processes, we normalize the initial value of the US productivity shock to $Z(0) = 1$ and the US demand shock to $Q_{US}(0) = 1$. We then set $Q_j(0)$ to be equal to country j's GDP relative to US GDP, $\forall j$. Finally, we take wages as exogenous and calculate them as real GDP per unit of equipped labor from Klenow and Rodríguez-Clare (2005), an average over the period 1995-2000. Appendix Table D.1 shows the results for each of the top ten host countries for US FDI.

It remains to calibrate the taste shifters λ_{ijk} and the parameters related to the costs of MNE expansion. These costs are: the fixed and sunk costs of affiliate opening, f_j^h and F_j^h, for $j = 1, ...10$, respectively; the fixed and sunk costs of affiliate exports, f_{jk}^e and F_{jk}^e, for $j = 1, ...10$, $k \neq j$, and $k = US$, respectively; and the iceberg trade costs of affiliate exports, τ_{jk}, for $j = 1, ...10$, $k \neq j$, and $k = US$.

Due to data limitations, we need to make some symmetry assumptions.[16] First, to represent possible taste differences between domestic goods and goods produced by foreign firms, we assume that $\lambda_{kkk} = 1$ and $\lambda_{ijk} = \lambda_j \neq 1$, for $i = US$ and $\forall k$. These taste shifters allow us to generate different market shares for domestic firms and US multinationals in a host country. Second, we assume that the fixed and sunk costs of affiliate exports are symmetric across all destination countries, other than the United States: $f_{jk}^e = f_j^e$ and $F_{jk}^e = F_j^e$, for $j = 1, ...10$, $k \neq j$, and $k \neq US$. Third, we assume that iceberg trade costs for destinations for which we do not have any bilateral affiliate export data are proportional to bilateral distance and to an exporter-specific dummy which is chosen to exactly match the aggregate export share from country j to all destinations.[17]

Additionally, since aggregate demand grows over time ($\mu_j > 0$, $\forall j$), we assume that the fixed and sunk costs of MNE activities in each host country j also grow at the deterministic rate μ_j. Hence we calibrate the initial value of the fixed and sunk cost for each host country. Without this growth adjustment, frictions to MNE activities would become irrelevant to the firm's decision over long time horizons; apart from this, the adjustment does not affect any other property of the model.

We are left with 117 parameters to calibrate for which we target 117 moments from the data. The

[16] As mentioned in Section 2.1, the BEA data do not report affiliate exports by destination country, except for the United States, and for a handful of countries (Canada, Japan, and the United Kingdom) in benchmark-year surveys.

[17] The distance elasticity is calculated by running a standard gravity equation with two sets of fixed effects and assuming that the trade elasticity is 4.

model does not have a one-to-one mapping from each parameter to each moment. Even though the calibration is done jointly, thanks to the model's closed-form solutions is relatively easy to isolate the moment that drives the identification of a given parameter. More precisely, the intensive margin of exports (i.e., export sale shares) drives the identification of the iceberg trade cost τ_{jk}, while affiliate entry rates and the share of affiliates in each country help identifying the sunk and fixed MNE entry costs, F_j^h and f_j^h, respectively.[18] Similarly, export entry rates and the share of exporting affiliates help identifying the sunk and fixed export costs, F_j^e and f_j^e, respectively. Finally, the ratio of affiliate horizontal sales to parent US sales helps identifying the taste shifters λ_j.

We choose the values of the parameters that fit best the data moments, for each country. To this end, we simulate the model 100 times, each time for a different realization of the vector of aggregate shocks. Each simulation amounts to solving the model for 1,000 firms and 30 years. Computationally, this amount to solve $N + N^2$ systems of four equations in four unknowns for each firm and time period, plus computing the equilibrium price index every period.

4.2 Model's fit

Table 4 reports simulated and data moments taking averages across the top-ten host countries and across years. The full set of simulated and data moments is reported in Appendix Tables D.4-D.8, while the calibrated parameters are shown in Appendix Tables D.2 and D.3. Table 4 shows that the model does a good job at matching both the static and dynamic targeted moments.

We also include in Table 4 two sets of non-targeted moments: static moments related to affiliate-size and affiliate-cost advantage, as well as exit moments.

The moments capturing affiliate-size and affiliate-cost advantage are related to the analytical predictions of the model described in Section 3.4. Proposition 1 implies that, controlling for the affiliates' host market, affiliates that export have larger horizontal sales than affiliates that don't export. In the data, the average horizontal sales of an affiliate that export from birth are 6.2 times larger than the average horizontal sales of an affiliate that never exports, averaging across affiliates' host markets. Our calibrated model generates an exporter premium among MNE affiliates of around seven. Similarly, the model predicts that affiliates that start exporting earlier in their life have larger horizontal sales than affiliates that start exporting later. In the data, the average horizontal sales of an affiliate that starts exporting early in life are 3.6 times larger than the average horizontal

[18] Since the share of affiliates, the affiliate entry rates, and the affiliate exit rates are linearly dependent, it is enough to target two out of the three moments. In the calibration, we target the share of affiliates and the affiliate entry rates, and leave the affiliate exit rates as non-targeted moments.

Table 4: Moments: model versus data, averages.

	data	model
Targeted Moments		
1. Static moments: intensive margin		
1.1 Affiliate sales share to host country	0.026	0.026
1.2 Affiliate sales share to the US	0.139	0.139
1.3 Affiliate sales share to third countries	0.288	0.296
1.4 Affiliate sales share to Canada	0.015	0.014
1.5 Affiliate sales share to the UK	0.069	0.087
1.6 Affiliate sales share to Japan	0.033	0.026
2. Static moments: extensive margin		
2.1 Share of MNEs with affiliates in j	0.287	0.283
2.2 Share of affiliates in j exporting to US	0.566	0.566
2.3 Share of affiliates in j exporting to third countries	0.650	0.646
3. Dynamic moments: entry		
3.1 Share of MNEs opening affiliates in j	0.035	0.021
3.2 Share of affiliates in j that start exporting to the US	0.030	0.024
3.3 Share of affiliates in j that start exporting to third countries	0.031	0.027
Non-Targeted Moments		
4. Static moments: size and cost advantage		
4.1 Exporter size advantage	6.11	7.03
4.2 Early-exporter size advantage	3.57	5.53
4.3 First-affiliate size advantage	2.57	2.13
5. Dynamic moments: exit		
5.1 Share of MNEs shutting down affiliates in j	0.113	0.083
5.2 Share of affiliates in j that stop exporting to the US	0.025	0.042
5.3 Share of affiliates in j that stop exporting to third countries	0.027	0.037

Note: Averages across host countries and years. Data moments for Japan, Canada, and the United Kingdom are averages over benchmark-year surveys only. Shares' denominators are: in 1.1, US parent's sales; and in 1.2-1.6, total horizontal sales of affiliates in j; in 2.1, the total number of MNEs; in 2.2 and 2.3, the total number of affiliates in j; in 3.1, total number of MNEs in period before entry; and in 3.2 (3.3), total number of affiliates in j in period before export entry into US (third countries); in 5.1, total number of affiliates in j in period before exit; and in 5.2 (5.3), the total number affiliate in j that export to the US (third countries) in the period before stopping the activity. In 4.1, exporter size advantage refers to the average size of exporting MNE affiliates relative to the average size of non-exporting MNE affiliates, an average across countries and years; in 4.2, affiliate early-exporter size advantage refers to the average size of exporting MNE affiliates that start exports early in life relative to the average size of exporting MNE affiliates that start exports later in life; in 4.3, first-affiliate size advantage refers to the ratio of the size of first foreign affiliate of a MNE (relative to GDP in the affiliate host market) to the size of subsequent foreign affiliates of the same MNE (relative to GDP in the affiliate host market, an average across MNEs and years; and in 4.4, first-affiliate cost advantage refers to the cost of starting a business in the country of the first foreign affiliate of a MNE relative to the cost of starting a business across the host countries of subsequent foreign affiliates of the same MNE, an average across MNEs and years. For moments in 4., size refers to horizontal affiliate sales; early vs late exporters refers to affiliates that are born with exports vs the ones that start exporting latert; and calculations in the calibrated model trim the upper and lower 10th decile of the simulated firm-level data.

sales of an affiliate that starts exporting later in life averaging across affiliates' host markets.[19] Our calibrated model generates an early-exporter premium of 5.5.

Additionally, the model has predictions about the expansion patterns of a MNE. Proposition 2 implies that MNEs open first their largest affiliates. In the data, on average, the horizontal sales of a first affiliate of a MNE are 2.6 times larger than the horizontal sales of the MNE's subsequent affiliates. The model generates a first-affiliate size premium of 2.1.[20]

Finally, as shown in the last panel of Table 4, the exit rates in the model are close to the ones we observe in the data. The model slightly under-predicts affiliate exit, and over-predicts exit from export markets.

4.3 The costs of MNE expansion

We now evaluate the magnitude of the costs of MNE expansion in time and space. Since model-based magnitudes are hard to interpret, in Table 5 we express the calibrated MNE costs as shares of firm revenues and as monetary values. Costs as shares of revenues by host country are reported in Appendix Tables D.10 and D.11.

On average, opening an affiliate involves spending a very low share of a firm's parent revenues. An affiliate's fixed operating costs range from about two percent of the affiliate's horizontal sales for the largest affiliates, to about 19 percent for the smallest affiliates. Affiliate export operations appear less costly than affiliate horizontal operations in monetary terms. As expected, affiliate exports to the United States have lower costs than exports to other destination markets, especially in terms of sunk costs. This result is intuitive as the US is the origin country of the affiliate.

The relative magnitudes of different fixed and sunk costs of affiliate operations and affiliate exports are informative about the heterogeneity of the frictions to MNE activities, both by country and by type of affiliate sales. Table 6 shows that opening affiliates in Brazil, Canada, China, Japan and Mexico is much more costly than starting export operations from them. Favorable trade regimes, such as NAFTA, or tax policies favoring exports but restricting horizontal FDI, as in China, can rationalize this pattern. Ratios lower than one for countries like Ireland and Singapore may be explained by favorable "tax-heaven"-like policies which attract FDI.

[19] We define early exporters as starting exports before age five, but the pattern is robust to the choice of the age cutoff. Appendix Figure D.1 shows that the patterns predicted by the model hold across the distribution of affiliates, not only on average.

[20] Proposition 2 also implies that MNEs open first affiliates located in countries that are less costly to enter. Even if measuring entry costs directly is hard, we proxy them with commonly used World Bank's Doing Business indicators and provide suggestive evidence supporting this prediction in Appendix Table D.9.

Table 5: Calibrated MNE costs: shares of sales and monetary values, average across host countries.

	As % of sales			In thousands $
	5th	50th	95th	
Sunk affiliate entry cost F_j^h, as % of parent US sales	0.05	0.02	0.00	161.0
Fixed affiliate entry cost f_j^h, as % of horizontal sales	18.7	12.2	2.30	1,525.1
Sunk export cost F_{jk}^e, as % of horizontal sales				
To United States	0.33	0.16	0.03	15.6
To other destinations	3.00	0.99	0.18	97.3
Fixed export cost f_{jk}^e, as % of exports sales				
To United States	12.7	10.1	1.7	98.5
To other destinations	12.8	11.6	3.3	814.6

Note: For F_j^h and f_j^h, we consider variables in the year of affiliate entry. For F_{jk}^e and f_{jk}^e, we consider variables in the year of affiliate first export to the destination. Percentiles are with respect to affiliate sales in the calibrated model. Cost shares in the model are converted into thousands of US dollars using sales values for the median affiliate in each of the top ten host countries included in the calibration, from the BEA, an averages across host countries. For confidentiality purposes, median sales are an average across the 9 observations around the median.

There is a large amount of heterogeneity in the fixed costs of setting up an affiliate relative to the fixed cost of exporting from it. Nonetheless, all the calibrated ratios are above one, indicating that the operating cost of horizontal activities is higher than the operating cost of export operations in all host countries.

The third and fourth columns in Table 6 illustrate the peculiarity of the United States as an export destination for affiliates of US MNEs. If the United States were an "average" affiliate export market, the reported ratios would be close to one. This is true only for the sunk export cost paid by affiliates located in the United Kingdom, for which the United States appears similar to other export destinations. Surprisingly, the United States seems to be a more expensive market for affiliates located in Canada and Mexico. This may well be because, for example, affiliates located in Canada also export large magnitudes to Mexico, which is also part of NAFTA and may be associated to lower costs than the United States.

5 Quantitative Analysis

Armed with the quantitative model, we explore the implications of counterfactual scenarios on aggregate firm dynamics. Since the top-ten host countries for US FDI in our sample include the United Kingdom, Ireland, Germany, and France, we use, as our first counterfactual exercise, the

Table 6: Calibrated MNE costs: by type, destination, and host country.

	F_j^h/F_j^e	f_j^h/f_j^e	$F_{jk}^e/F_{j,US}^e$	$f_{jk}^e/f_{j,US}^e$
Brazil	117	4.80	4.20	0.82
Canada	NaN	4.9	0.00	0.63
China	2.10	1.80	0.45	0.75
France	0.31	3.10	470	2.26
United Kingdom	0.01	2.80	1.01	1.91
Germany	0.15	2.80	30.2	2.45
Ireland	0.43	1.90	NaN	0.95
Japan	42.2	6.40	36.4	1.21
Mexico	12.6	4.70	0.06	0.70
Singapore	0.03	1.07	6.21	0.84

Note: In column 1 (column 2), the denominator is an average of the sunk (fixed) costs of exporting to the United States and to any other destination k, from country j. In column 3 (column 4), the ratio is between the sunk (fixed) export cost from j to any destination k, other than the United States, relative to the US.

possibility of the United Kingdom abandoning the European Union (EU), "Brexit". Different proposed implementations of Brexit have as common element the increase in export costs between the United Kingdom and other countries in the EU. In our model, this increase can be captured either as an increase in the iceberg trade cost, $\tau_{UK,j}$, an increase in the fixed export cost, $f_{UK,j}^e$, or an increase in the sunk export cost, $F_{UK,j}^e$, for j = France, Germany, Ireland. We can think about "shallow Brexit" scenarios, where only one type of friction is affected, or "deep Brexit" scenarios, where all the export barriers increase simultaneously. Additionally, in the Brexit context, we evaluate the importance of including the endogenous price response to the various shocks by comparing the aggregate dynamics of the model with and without endogenous prices. In our model, the magnitude of the price change is also informative about changes in welfare—i.e., the real wage.

In a second counterfactual, we raise the cost of MNE activities in the United Kingdom, captured in our model by the per-period cost of MNE operations,f_{UK}^h. We use this exercise to evaluate quantitatively the role played by the compound option structure of our model. That is, we evaluate the response to a cost shock in a calibrated model with and without export platforms.

Finally, we analyze the response of US MNEs to a restriction to "shipping jobs abroad". We model this scenario by increasing the costs of opening (F_j^h) and operating (f_j^h) US MNE affiliates abroad, alternately, for all host countries j.

For each counterfactual exercise, we simulate the calibrated model for 30 periods and impose a permanent change in (one of the) parameters at t=15.

5.1 Brexit

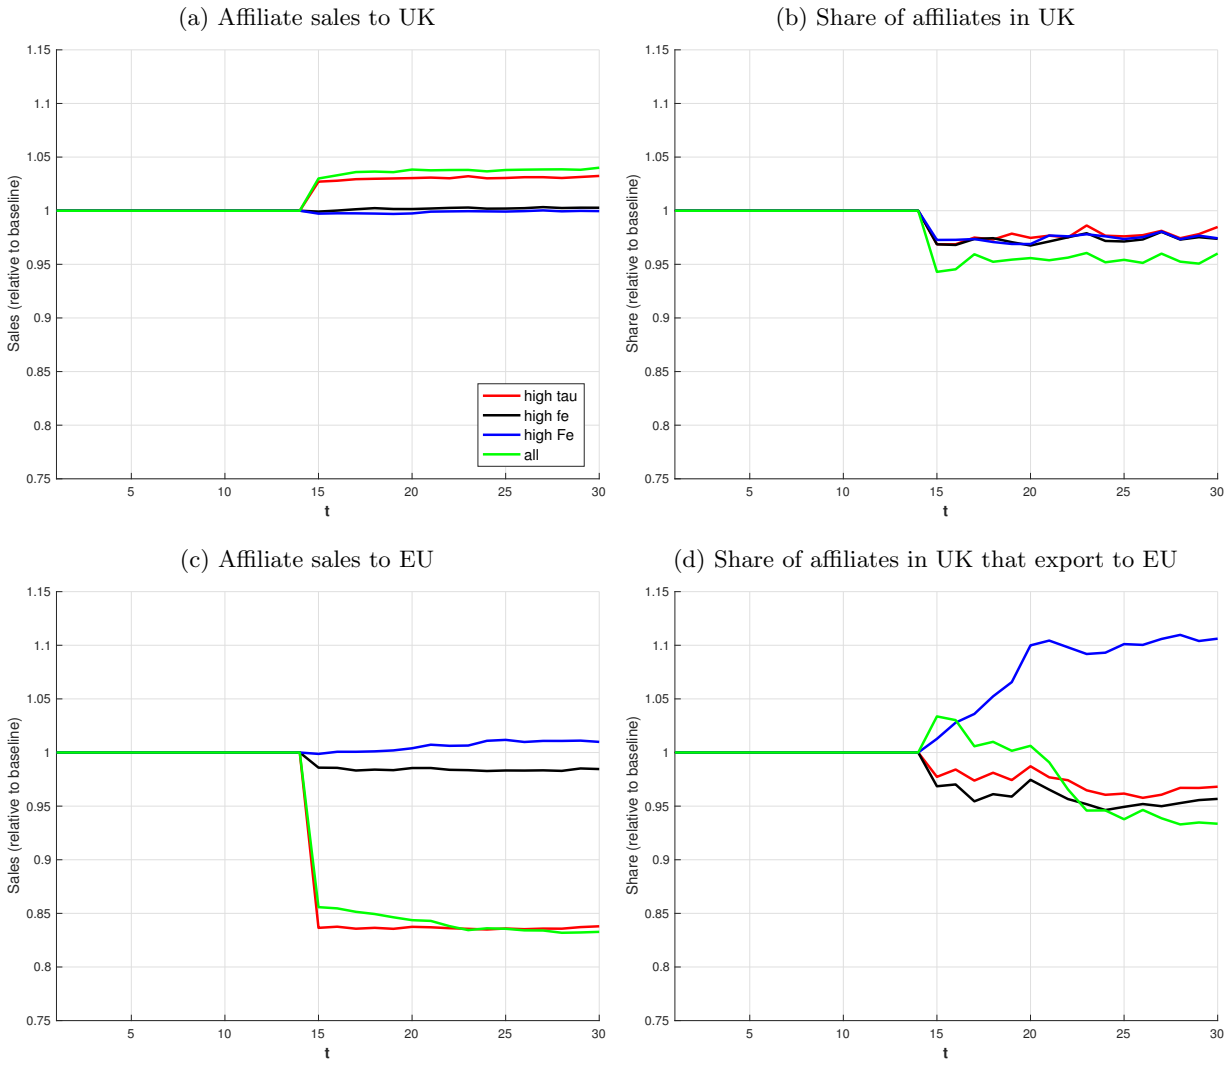

First, we increase, one at the time, the barriers to export from/to the United Kingdom to/from the European countries in our sample ("shallow Brexit"): $\tau_{UK,j}$, $f^e_{UK,j}$, and $F^e_{UK,j}$, for j = Ireland, Germany, and France. In order to make the results of the three exercises comparable, we increase each trade friction by an amount that results in a 20 percent increase in the total per-period cost of FDI, $\left(f^e_{UK,j} + \rho F^e_{UK,j}\right) \tau^{\eta-1}_{UK,j}$. For "deep Brexit", we increase all export barriers at once of the same amounts as in the "shallow Brexit" exercises.

Intuitively, increasing trade barriers between the United Kingdom and other EU countries has two main effects. First, exporting from the United Kingdom to the EU becomes more costly, so that export sales from UK-based affiliates to countries in the EU decline, decreasing the incentive to open affiliates in the United Kingdom due to the smaller, and more costly, available network of exporting destinations. Second, exporting from the EU to the United Kingdom also becomes more costly, so that export sales from affiliates in EU countries to the United Kingdom also decline, decreasing the incentive to open affiliates in those countries. These are static, partial equilibrium effects. In addition, increases in trade costs also affect the affiliate export band of inaction, which in turn affects affiliate export entry and exit. Finally, increases in trade frictions have the effect of raising the price index in the destination countries, encouraging more export entry from the United Kingdom. Our quantitative analysis captures the effects of all these forces.

Figure 4 shows the effects of "shallow Brexit" on affiliates in the United Kingdom. Results are presented as deviations from the baseline scenario—i.e., the calibrated model. In all cases, higher trade costs between the United Kingdom and other EU countries reduce the share of affiliates based in the United Kingdom. Before the shock, about half of US MNEs had affiliates located in the United Kingdom, as shown in Appendix Table D.6. All three "shallow Brexit" shocks cause a permanent decrease in the share of US MNE affiliates in the United Kingdom of around three percent (Figure 4b). The cumulative increase of all frictions ("deep Brexit") drives a decrease in the share of affiliates in the United Kingdom of five percent. Naturally, the affiliates that exit are the smallest and account for only a few percentages of US affiliate sales in the United Kingdom. This observation, together with the contemporaneous increase in the price index in the United Kingdom, shown in Figure 7, explains the somewhat counterintuitive result in Figure 4a whereby affiliates sales to the United Kingdom increase when variable trade costs increase. The effects of changing trade costs on horizontal activities in the United Kingdom are small, since trade frictions affect those activities only indirectly through the compound option.

The lower panels of Figure 4 shows the effect of "shallow Brexit" on the export sales and export

Figure 4: Brexit: US MNEs' affiliates in the United Kingdom.

Note: "high X" refers to an increase in the barrier X from/to United Kingdom to/from country j ("shallow Brexit"). "All" refers to increasing all three export barriers from/to the United Kingdom to/from j at once ("deep Brexit"). Country j refers to Ireland, Germany, and France.

participation rates of UK-based affiliates of US MNEs to Ireland, Germany, and France. This plot illustrates how different frictions to MNE activities have very different quantitative effects on affiliate exports and participation rates, even if the changes in those frictions are associated with the same increase in the per-period cost of FDI. More precisely, the observed decline in export sales, when either $f^e_{UK,j}$ or $\tau^e_{UK,j}$ increase, comes from affiliates that stop exporting. The decline in export sales also includes an intensive-margin decline for the case of a shock to $\tau_{UK,j}$. Consequently, the change that has the highest impact on affiliate export sales is the increase in the per-period iceberg trade cost: an increase in $\tau_{UK,j}$ corresponding to a 20 percent increase in the cost of FDI

produces a 15 percent decline in UK-based affiliates' export sales, a much larger decline than the one produced by increases in fixed export costs. Conversely, an increase in the sunk export cost, $F^e_{UK,j}$, produces an (a small) increase in affiliate export sales. As Appendix Figure E.5 illustrates, an increase in the sunk export cost increases the export band of inaction, driving a decline in both affiliate export entry and exit rates. The decline in the exit rate is the most pronounced in this scenario, giving rise to the increase in affiliate export sales observed in Figure 4c, and in the share of exporting affiliates observed in Figure 4d. Except for the case of an increase in the sunk export cost, the Brexit shock has the effect of reducing the share of affiliates that export. The increase in fixed export cost produces the largest decline in the export participation share because this cost is intimately related to the affiliates' decision to exit a market.

The case of ''deep Brexit" is interesting as it shows important differences between the aggregate dynamics after a shock in the short and long run. In particular, in the short run the effect of the decrease in sunk export costs dominates and the share of affiliates in the United Kingdom that export to EU increases. 15 periods after the shock, this share decreases by around seven percentage points relative to the pre-shock levels.

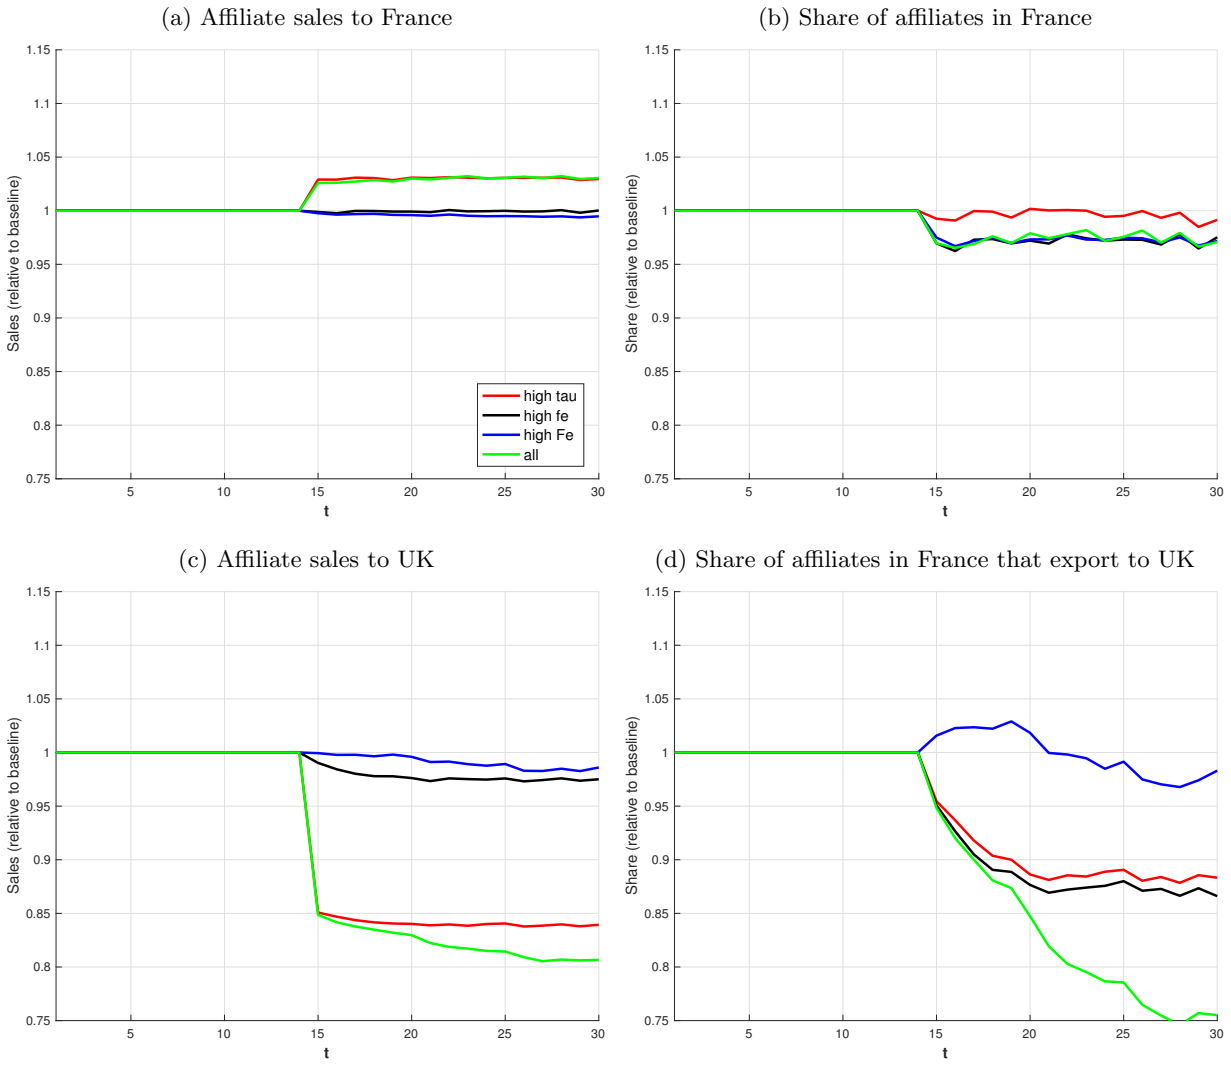

The results for affiliates located in Ireland, Germany, and France are qualitatively similar to the ones for affiliates located in the United Kingdom. There are, however, some important quantitative differences. We show the results for affiliates of US MNEs located in France in Figure 5, and relegate the results for Ireland and Germany to Appendix Figures E.3 and E.4, respectively.

As expected, higher trade costs between France and the United Kingdom reduce MNEs' incentives to locate in France, and the share of affiliates of US MNEs located in France declines. As already seen for the United Kingdom, this decline in the extensive margin is accompanied by an increase in the intensive margin of horizontal sales in France for the scenario in which $\tau_{UK,FR}$ increases. This increase is driven by the corresponding increase in the price index in France. Naturally, the share of affiliates in France that export to the United Kingdom as well as their export sales drop after the Brexit shock in almost all specifications. An increase in the sunk export cost generates a non-monotonic response of the share of exporting affiliates, which first increases (due to a decline in exit rates) and then decreases.

Summing up, the results in Figures 4 and 5 show that increasing a variable, fixed, or sunk cost of export has a *quantitatively* different effect on aggregate firms' dynamics. Even though the increase in the per-period costs of FDI is the same in all cases, the type of trade barriers that changes matters for both the extensive and intensive margins of firms' decisions.

The tractability of our model allows us to solve numerically for the aggregate price index in a

Figure 5: Brexit: US affiliates in France.

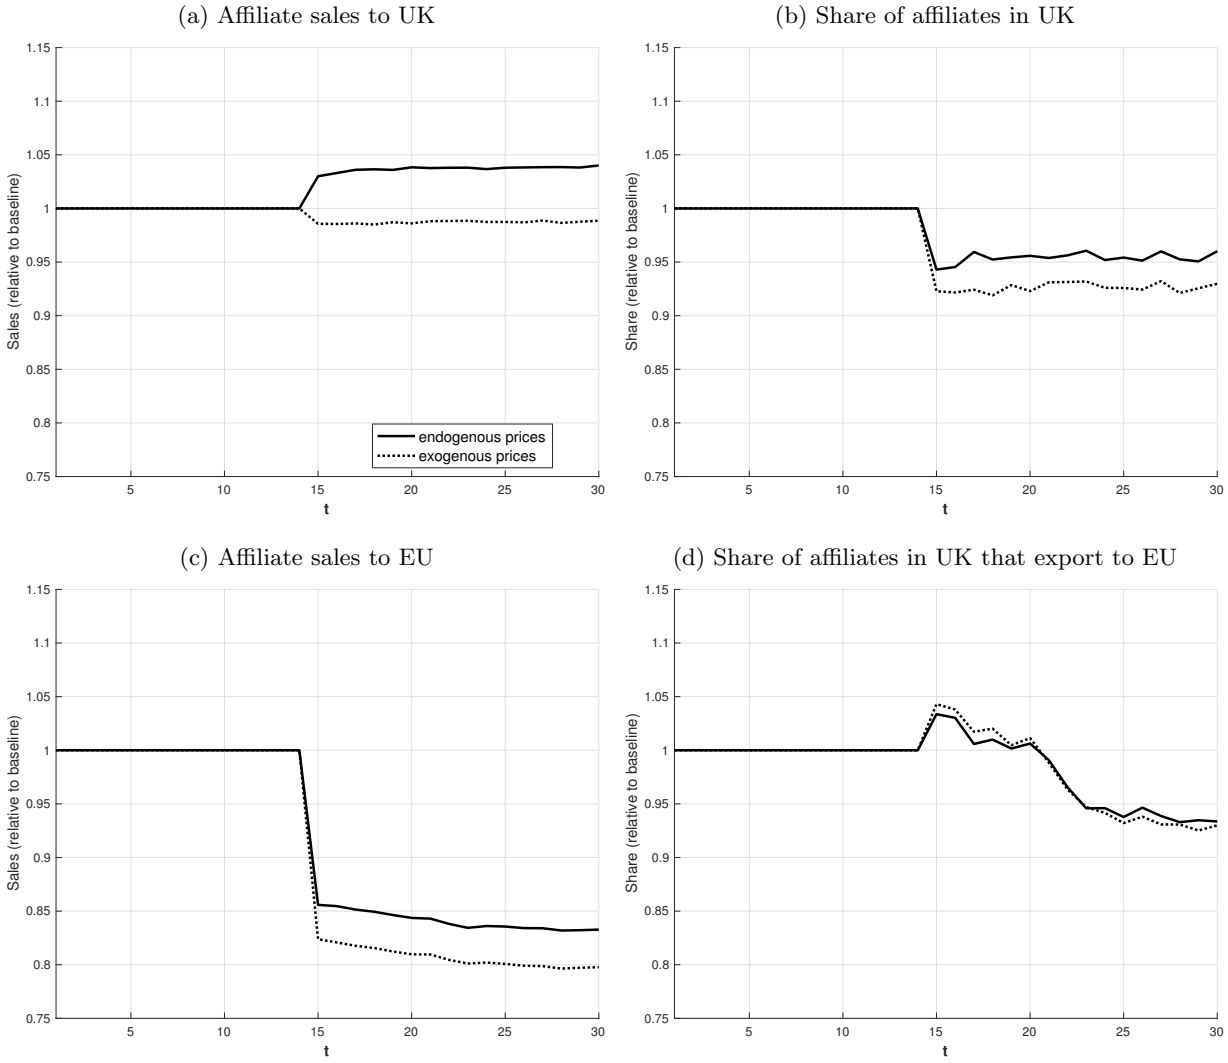

Note: "high X" refers to an increase in the barrier X from/to United Kingdom to/from country j ("shallow Brexit"). "All" refers to increasing all three export barriers from/to the United Kingdom to/from j at once ("deep Brexit"). Country j refers to Ireland, Germany, and France.

multi-country dynamic setup, so that the results of our counterfactual exercises incorporate the effects of changes in the price indexes on firms' decisions. How important are these price effects *quantitatively*? Are they strong enough to affect the aggregate dynamics of MNEs?In Figure 6, we show the dynamics of aggregate outcomes after the "deep Brexit" shock under endogenous and exogenous prices. It is clear that the endogenous response of prices acts as a buffer to the decrease in the affiliate horizontal and export sales as well as to the decrease in the share of US MNEs operating in the United Kingdom. In the case of horizontal sales shown in Figure 6a, the effect is

strong enough to reverse the pattern from a two-percent decrease to a three-percent increase.[21]

Figure 6: Brexit: US affiliates in the United Kingdom. Endogenous vs exogenous prices.

Note: The shock refers to increasing all three export barriers from/to the United Kingdom to/from country j at once ("deep Brexit"). Country j refers to Ireland, Germany, and France.

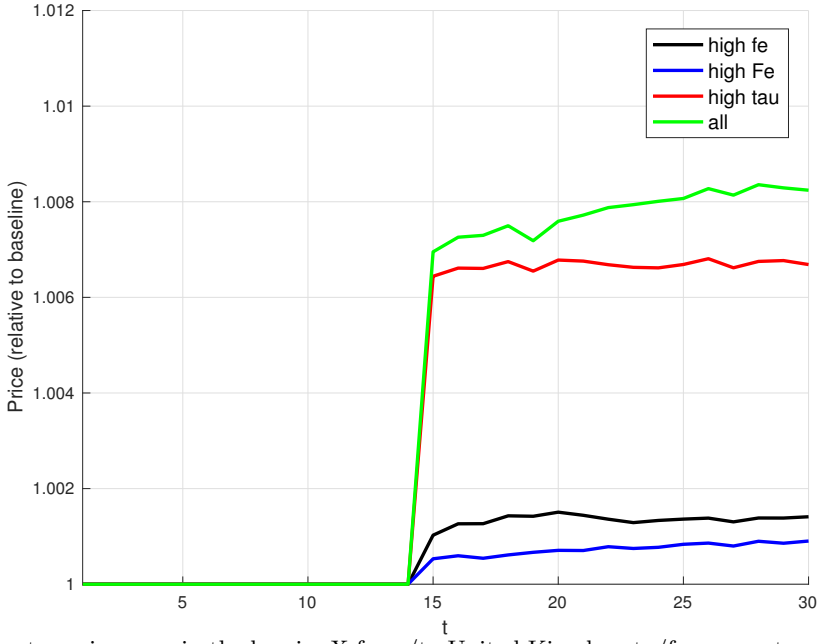

It is straightforward to evaluate the welfare losses from the different Brexit scenarios from our counterfactual price changes.[22] Figure 7 shows that, as expected, the largest welfare loss is experienced under "deep Brexit", with a decrease in real income that goes from 0.7 percent in the short run to more than 0.8 percent after 15 years. In the context of "shallow Brexit", an increase in variable

[21] Appendix Figure E.1 shows results with exogenous prices for US MNE affiliates in the United Kingdom, for all Brexit counterfactuals.

[22] Since we assume that wages are exogenous, it is important to point out that our welfare calculations should be interpreted as upper bounds of losses from the effect of Brexit on MNEs.

trade costs produces the highest loss, while an increase in sunk export costs produces the smallest loss. These are not small magnitudes given that our model is restricted to the behavior of MNEs from the United States. The increase in trade barriers would presumably affect local and other non-US MNE exporters. Appendix Figure E.2 shows the change in prices after each Brexit shock, for each of the countries involved. As expected, changes in prices (and corresponding welfare losses) are highest for Ireland, whose economy is deeply connected to the UK economy.

Figure 7: Brexit: Price changes in the United Kingdom.

Note: "high X" refers to an increase in the barrier X from/to United Kingdom to/from country j ("shallow Brexit"). "All" refers to increasing all three export barriers from/to the United Kingdom to/from j at once ("deep Brexit"). Country j refers to Ireland, Germany, and France.

Our Brexit counterfactual illustrates the importance of considering the global structure of the MNE to accurately assess the consequences of shocks to the costs of MNE expansion. In a model in which MNEs could only serve the host market of operation, one would erroneously conclude that Brexit, in the form of higher trade barriers, would not have any impact on the behavior in time and space of US MNEs. We explore in more detail the role played by export platforms in the next counterfactual.

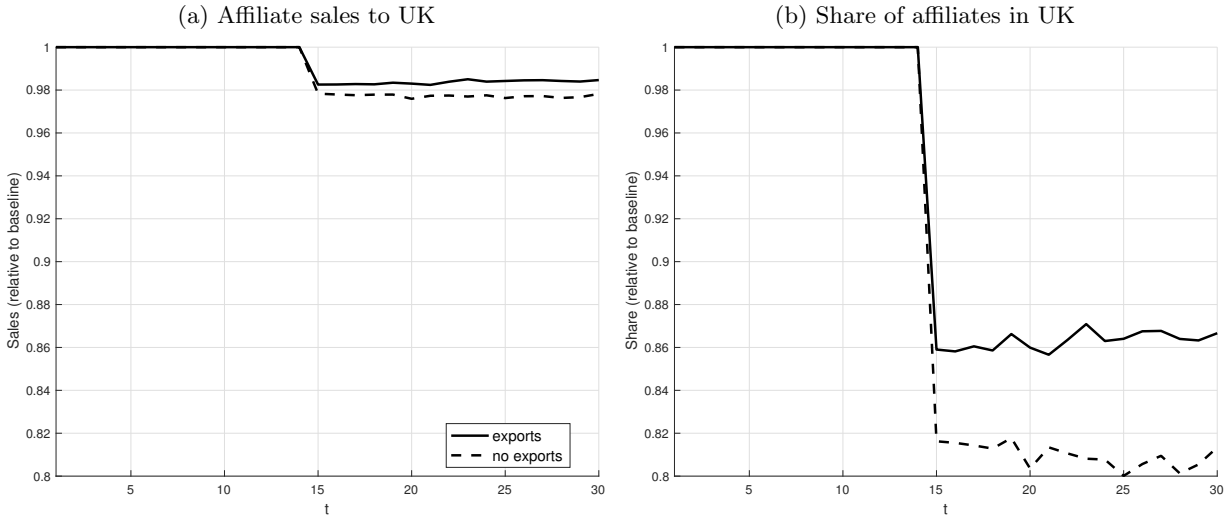

5.2 The role of the compound option

We now evaluate quantitatively the role played by the compound option structure of our model. To such end, we analyze the effects of an increase in the barriers to MNE activities in a model

with and without the compound option—or analogously, a model with and without MNE affiliates' exports. We use again the case of Brexit and increase the fixed cost of MNE activities in the United Kingdom, f^h_{UK}, by 20 percent.

As our baseline model without the compound option, we use a calibrated version of the model where affiliates of US MNEs cannot sell to countries other than their host country (i.e., no exports). In this calibration, we target the same moments as for the model with exports (moments 1.1, 2.1, and 3.1 in Table 4), for the United Kingdom.[23]

Figure 8: The role of the compound option: US affiliates in the United Kingdom.

Note: At $t = 15$, the fixed cost of MNE activities in the UK, f^h_{UK} increases by 20 percent. "Exports" refers to the calibrated (baseline) model where MNE affiliates can export, while "no exports" refers to the calibrated model where MNE affiliates cannot export. Results are shown as deviations from the calibrated models with and without export platforms, respectively.

Figure 8 shows the dynamics of horizontal affiliate sales and the share of US affiliates in the United Kingdom after the shock to f^h_{UK} at $t = 15$. Results are shown as deviations from the respective baselines—i.e., the calibrated models with and without the compound option. In the model with only horizontal sales (dashed lines), MNEs do not have the option of exporting part of their output. Hence, the incentives to open an affiliate in a country coming from the possibility of using that host country as an export platform are precluded. Without the possibility of exporting to other markets from the United Kingdom, one would conclude that an increase in barriers to MNE activities in the United Kingdom would decrease the presence of US affiliates in the country by 25 percent more

[23] The calibrated model without export platforms fits worse than the baseline model the relevant data moments. While the share of MNEs with affiliates in the United Kingdom is 53.7 (55.4) percent in the model without exports (data), the share of MNEs opening affiliates the United Kingdom is 2.2 (6.9) percent in the model (data), and the share of UK affiliates shutting down is 8.8 (4.5) percent in the model (data).

(in the short run) than in the case in which exports are possible. Moreover, in the model without exports, this share would continue with its decline, while in the model with export platforms the share of US affiliates would start increasing in the long run.

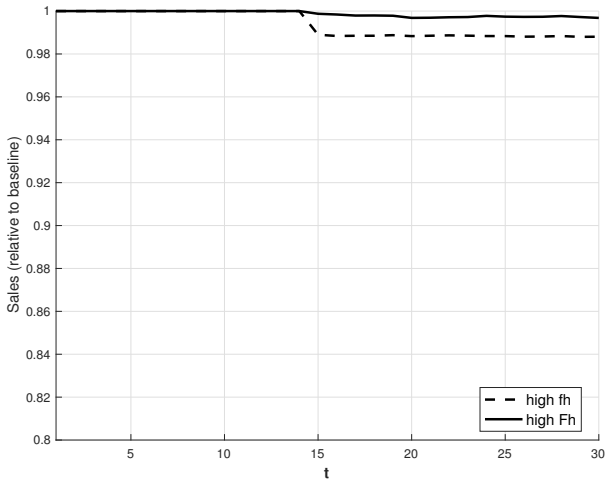

The result in Figure 8, once again, points to the importance of the compound option structure when making dynamic quantitative predictions on the effects of shocks to MNE activities.

5.3 The rise of US protectionism

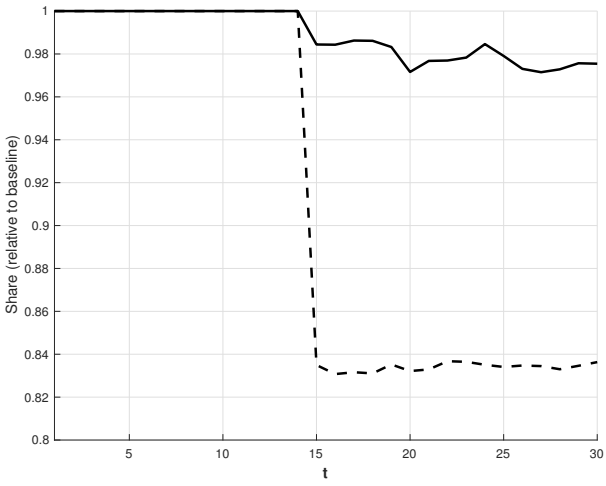

We now show other possible counterfactuals that can be performed with our calibrated model. In particular, we evaluate the effects of increasing the costs for US MNEs of "shipping jobs abroad". To such end, we increase by 20 percent the per-period cost of operating affiliates abroad, f_j^h, in all host countries j. Alternately, we increase by 20 percent the one-time cost of starting foreign operations, F_j^h, in all countries j. Figure 9 shows the dynamics of total foreign sales of US MNEs and the share of affiliates of US MNEs in an average host country.

Figure 9: Increasing costs of US MNE operations: Foreign affiliates of US MNEs.

(a) Total foreign US affiliate sales

(b) Avg share of US affiliates

Note: At $t = 15$, the fixed (sunk) cost of MNE activities from the United States, f_j^h (F_j^h) increases by 20 percent, for all j. Figure (9a) aggregates the sales of all foreign affiliates of US MNEs, while Figure (9b) shows the share of affiliates of US MNEs in an average host country.

As a result of an increase in per-period costs, the share of US MNEs operating foreign affiliates declines about 17 percent. Since the affiliates that exit are the smallest ones, total affiliate sales decline only about 1 percent. An increase in the sunk cost of setting up an affiliate generates quantitatively smaller effects. The average increase in prices abroad produced by the increase in

sunk MNE cost, however, is twice as large as the increase produced by the increase in fixed MNE costs (0.30 vs 0.15 percent).

6 Conclusions

This paper studies the expansion patterns of the multinational enterprise (MNE) in time and space. Our facts, documented using a long panel of US MNEs, guide us on the development of a dynamic model of the MNE that is tractable and, at the same time, rich enough to capture the complexity of MNE activities observed in the data. The model features heterogeneity in firm productivity, persistent aggregate shocks, and a rich structure of MNE costs. Importantly, MNE affiliates can decouple their location of production from the one of sales, and endogenously choose to enter or exit both the host and the export markets. The novel feature of the model is the introduction of a compound option formulation, which is key to quantifying the costs to MNE expansion. Our counterfactual exercises reveal that this compound option structure is important to understand the reallocation of MNE activity in time and space, after a shock. Moreover, the nature of the frictions to MNE activities (variable, fixed, or sunk) is important to understand aggregate firm dynamics after a shock.

Appendix

A Data Description

Reporting thresholds. The BEA collects firm-level data on the operations of US multinational enterprises (MNEs) in its annual surveys of US direct investment abroad. All US-located firms that have at least one foreign affiliate and that meet a minimum size threshold are required by law to respond to these surveys. These minimum size thresholds are in terms of affiliate sales and differ over time. In general, reporting thresholds increased in recent years, reaching US$60 millions by 2011. Additionally, benchmark survey years (i.e., years in which the survey is more comprehensive), which occur every 5 years, have lower reporting thresholds. Table A.1 shows the reporting thresholds for the years in our sample.

Table A.1: BEA minimum survey exemptions levels.

survey year	Minimum exemption levels (in U$ millions)	survey year	Minimum exemption levels (in U$ millions)
1987-88	10	2000-03	30
1989	**3**	**2004**	**25**
1990 -93	15	2005-07	40
1994	**3**	2008	60
1995-98	20	**2009**	**25**
1999	**7**	2010-11	60

Note: Exemption levels are for majority-owned foreign affiliates. Benchmark survey years are **in bold**.

Tax havens. Our sample contains affiliates that do not operate in tax haven countries. Affiliates in tax haven countries are likely to open for different reasons than production purposes, and to be subject to different cost structures than affiliates in non-tax haven countries. We exclude countries defined as tax havens by Gravelle (2015), except for Ireland, Switzerland, Hong Kong, and Singapore that meet some of the criteria for tax haven status but also have a substantial amount of US MNE production. Table A.2 reports the list of countries that we exclude from our sample.

Industry classification. Each foreign affiliate is assigned an industry classification based on its primary activity according to the BEA International Surveys Industry (ISI) system, which closely follows the 3-digit Standard Industrial Classification (SIC) system. The BEA uses 3-digit SIC-

Table A.2: Tax haven countries excluded from our sample.

Anguilla	Turks and Caicos	Monaco
Antigua and Barbuda	US Virgin Islands	San Marino
Aruba	Belize	Maldives
Bahamas	Costa Rica	Mauritius
Barbados	Panama	Seychelles
British Virgin Islands	Bermuda	Bahrain
Cayman Islands	Macau	Cook Islands
Dominica	Andorra	Marshall Islands
Grenada	Channel Islands	Samoa
Montserrat	Cyprus	Nauru
Netherlands Antilles	Gibraltar	Niue
St. Kitts and Nevis	Isle of Man	Tonga
St Lucia	Liechtenstein	Vanuatu
St Vincent and Grenadines	Malta	Liberia

Note: From Gravelle (2015).

based ISI codes for years prior to 1999. From 1999 onward, they use 4-digit NAICS-based ISI codes. For consistency, we convert the NAICS-based codes to 3-digit SIC-based ISI codes for the relevant years.

Unit of observation. According to the BEA definition, an affiliate is a business enterprise in a given industry operating in a particular host country; it thus can operate several plants in different locations within the host country. The BEA rules permit consolidated reporting for distinct plants located in the same country that operate in the same narrowly defined industry or otherwise are integral parts of the same business operation. We consolidate observations of enterprises belonging to the same parent company and operating in the same country and 3-digit industry. We group these enterprises' activities together and refer to them as a single affiliate.

Industry fe	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes	No	Yes

Note: Observations at the affiliate-year level, for new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. The dependent variable *affiliate to parent sales* refers to affiliate sales relative to the domestic sales of the US parent. First affiliate refers to the first foreign affiliate opened by the parent, while subsequent affiliate refers to second or higher. GVC affiliate refers to affiliates with positive intra-firm trade, while non-GVC affiliate refers to affiliates with zero intra-firm trade. M&A affiliate refers to affiliates created through a merger or acquisition of an existing firm, while greenfield affiliate refers to a new firm. All specifications include country-year fixed effects. Standard errors, clustered at the parent level, are in parenthesis. Levels of significance are denoted $^{***}p < 0.01$, $^{**}p < 0.05$, and $^{*}p < 0.1$.

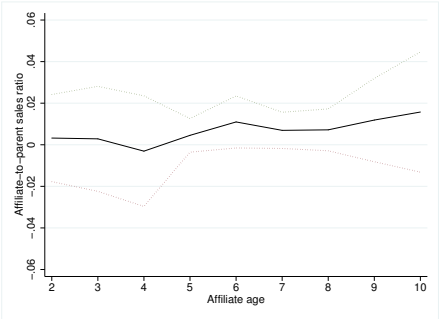

Table B.2: Intensive and extensive margins of sales. OLS.

Dependent variable	Intensive margin of sale shares				Extensive margin of sale shares

Note: Observations at the affiliate-year level, for new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. In columns (1)-(4), the dependent variable is horizontal (export) sales, as a share of total affiliate's sales, for affiliates born with only horizontal (export) sales; in columns (5)-(8), the dependent variable is the share of affiliates born with only horizontal (export) sales. Standard errors, clustered at the parent level, are in parenthesis. Levels of significance are denoted $^{***}p < 0.01$, $^{**}p < 0.05$, and $^{*}p < 0.1$.

Figure B.2: Intensive and extensive margins of sales, by activity type. Pure-type affiliates at birth.

(a) Affiliate sales shares (intensive margin)

(b) Share of affiliates (extensive margin)

Notes: Sample of new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. Horizontal and export sales refer, respectively, to sales to the market where the affiliate is located, and to sales to markets outside the local market. (B.2a): average sales, as a share of total affiliate sales, include affiliates with positive horizontal and export sales, respectively, for the subset of affiliates with only horizontal and only export sales at birth, respectively). (B.2b): number of affiliates, as a share of the total number of affiliates, include affiliates with positive horizontal and export sales, respectively.

C Model's Solution

C.1 Solution to the dynamic firm's problem

The compound option structure of the model implies that it can be solved backwards. We start from the problem of a firm that already has an affiliate in country j and has to decide whether to

Note: Probability of opening affiliates in the top-ten most popular destinations for US MNEs. Conditional probabilities refer to the probability of observing a MNE opening an affiliate in country i given that the parent already has an affiliate in a "similar" country. The sample is restricted to parents with at least five (ten) affiliates worldwide in the upper (lower) panel. Conditional probabilities in ***bold*** are not significantly different from the relevant unconditional probability.

Table B.5: MNE shock structure, OLS.

Dependent variable	log of horizontal affiliate sales			
country-industry fixed effect	yes	yes	yes	yes
US GDP	yes	yes	yes	yes
Host country GDP	yes	yes	yes	yes
parent fixed effect	no	yes	yes	no
parent sales	no	no	yes	yes
affiliate fixed effect	no	no	no	yes
Adjusted R-squared	0.24	0.27	0.29	0.79

Notes: Sample of *all* affiliates born during the sample period. Number of observations: 153,773.

Figure B.3: Sales and affiliate entry age, by activity type.

Notes: Sample of new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. Average horizontal (export) sales shares, by affiliate first age with positive horizontal (export) sales.

export to any country $k \neq j$. Once this problem is solved, the value of an affiliate in j is determined. Then we can solve the problem of a firm that has to decide whether to open an affiliate in each country j. For each step of the solution, we follow the method outlined in Dixit and Pindyck (1994).

To solve the affiliate export problem, we start by solving for the value functions $V^o_{jk}(z, X, \mathbf{Q})$ and $V^o_{jk}(z, X, \mathbf{Q})$ in their continuation region. Writing the Bellman equation in (14) that describes the value of the option to export to country k for a firm with an affiliate in country j in the continuation

region, taking the limit as $\Delta t \to 0$, and applying Ito's Lemma, yields the no-arbitrage condition

$$\rho V^o_{jk}(z, Y_k) = \tilde{\mu}_k Y_k V'^o_{jk}(z, Y_k) + \frac{\tilde{\sigma}^2_k}{2} Y^2_k V''^o_{jk}(z, Y_k), \tag{C.1}$$

where we acknowledge that the option value of exporting to k only depends on the realization of the composite shock Y_k. Guessing a solution for the value function and applying the method of undetermined coefficients, the value of the option of exporting to country k for an affiliate in country j has general solution given by

$$V^o_{jk}(z, Y_k) = A^o_{jk}(z) Y^{\alpha_k}_k + B^o_{jk}(z) Y^{\beta_k}_k, \tag{C.2}$$

where $\alpha_k < 0$ and $\beta_k > 1$ are the roots of $\frac{1}{2}\tilde{\sigma}^2_k \xi^2 + \left(\tilde{\mu}_k - \frac{\tilde{\sigma}^2_k}{2}\right)\xi - \rho = 0$. As $Y_k \to 0$, the option of exporting becomes worthless, so it must be that $A^o_{jk}(z) = 0$. Conversely, the option of exporting becomes more attractive as Y_k increases, so it must be that $B^o_{jk}(z) > 0$.

Similarly, writing the Bellman equation in (15) that describes the value of exporting to country k from an affiliate in country j in the continuation region, taking the limit as $\Delta t \to 0$, and applying Ito's Lemma, yields the no-arbitrage condition

$$\rho V^e_{jk}(z, Y_k) = \pi_{jk}(z, Y_k) - f^e_{jk} + \tilde{\mu}_k V'^e_{jk}(z, Y_k) + \frac{\tilde{\sigma}^2_k}{2} Y^2_k V''^e_{jk}(z, Y_k). \tag{C.3}$$

Guessing a solution for the value function and applying the method of undetermined coefficients, the value of the option of exporting to country k for an affiliate in country j has general solution given by

$$V^e_{jk}(z, Y_k) = A^e_{jk}(z) Y^{\alpha_k}_k + B^e_{jk}(z) Y^{\beta_k}_k + \frac{\pi_{jk}(z, Y_k)}{\rho - \tilde{\mu}_k} - \frac{f^e_j}{\rho}. \tag{C.4}$$

Notice that, as $Y_k \to 0$, there is value from the possibility of endogenously stopping to export, so it must be that $A^e_{jk}(z) > 0$. Also, as Y_k increases, the value of exports converges to the discounted profit flow (i.e., there is no further expansion option), so it must be that $B^e_{jk}(z) = 0$.

To completely solve the affiliate export problem, we need to solve for the policy functions, which are thresholds for the realizations of the composite shock that induce the affiliate to start and stop exporting. For each country pair (j, k) and for each firm with productivity z, the parameters $B^o_{jk}(z) > 0$, $A^e_{jk}(z) > 0$, and the export entry and exit thresholds, denoted by Y^{OE}_{jk} and Y^{EO}_{jk}, respectively, can be recovered from the following system of value-matching conditions,

$$V^o_{jk}(z, Y^{OE}_{jk}) = V^e_{jk}(z, Y^{OE}_{jk}) - F^e_{jk} \quad \text{and} \quad V^o_{jk}(z, Y^{EO}_{jk}) = V^e_{jk}(z, Y^{EO}_{jk}), \tag{C.5}$$

and smooth-pasting conditions,

$$V'^{o}_{jk}(z, Y^{OE}_{jk}) = V'^{e}_{jk}(z, Y^{OE}_{jk}) \quad \text{and} \quad V'^{o}_{jk}(z, Y^{EO}_{jk}) = V'^{e}_{jk}(z, Y^{EO}_{jk}), \tag{C.6}$$

where $V'(\cdot)$ denotes the derivative of a value function with respect to the composite shock.

To determine the value of an affiliate in j, we still need to solve for the value of horizontal sales. Writing the Bellman equation in (13) that describes the value of horizontal sales for an affiliate in country j in the continuation region, taking the limit as $\Delta t \to 0$, and applying Ito's Lemma, yields the no-arbitrage condition

$$\rho V^{h}_{j}(z, Y_j) = \pi_{jj}(z, Y_j) - f^{h}_{j} + \tilde{\mu}_j Y_j V'^{h}_{j}(z, Y_j) + \frac{\tilde{\sigma}^2_k}{2} Y^2_j V''^{h}_{j}(z, Y_j). \tag{C.7}$$

Guessing a solution for the value function and applying the method of undetermined coefficients, the value of horizontal sales for an affiliate in country j has general solution given by

$$V^{h}_{j}(z, Y_j) = A^{h}_{j}(z) Y^{\alpha_j}_{j} + B^{h}_{j}(z) Y^{\beta_j}_{j} + \frac{\pi_{jj}(z, Y_j)}{\rho - \tilde{\mu}_j} - \frac{f^{h}_{j}}{\rho}. \tag{C.8}$$

Notice that, as $Y_j \to 0$, there is value from the possibility of shutting down the affiliate, so it must be that $A^{h}_{j}(z) > 0$. As Y_j increases, the value of horizontal sales converges to the discounted profit flow, so it must be that $B^{h}_{j}(z) = 0$.

The value of an affiliate in country j, $V^{a}_{j}(z, \mathbf{Y})$ is completely characterized up to the option value parameter $A^{h}_{j}(z)$:

$$V^{a}_{j}(z, \mathbf{Y}) = A^{h}_{j}(z) Y^{\alpha_j}_{j} + \frac{\pi_{jj}(z, Y_j)}{\rho - \tilde{\mu}_j} - \frac{f^{h}_{j}}{\rho} + \sum_{k \in \mathcal{A}_j(z)} \left[\frac{\pi_{jk}(z, Y_k)}{\rho - \tilde{\mu}_k} - \frac{f^{e}_{jk}}{\rho} + A^{e}_{jk}(z) Y^{\alpha_k}_{k} \right] + \sum_{k \notin \mathcal{A}_j(z)} \left[B^{o}_{jk}(z) Y^{\beta_k}_{k} \right], \tag{C.9}$$

where $\mathcal{A}_j(z)$ denotes the set of export markets in which an affiliate of a firm with productivity z located in country j exports.

To solve the affiliate opening problem, we still need to solve for the option value of opening an affiliate, and for the policy functions. Writing the Bellman equation in (12) that describes the value of the option to open an affiliate in country j in the continuation region, taking the limit for $\Delta t \to 0$, and applying Ito's Lemma, yields the no-arbitrage condition

$$\rho V^{o}_{j}(z, Y_j) = \tilde{\mu}_j Y_j V'^{o}_{j}(z, Y_j) + \frac{\tilde{\sigma}^2_j}{2} Y^2_j V''^{o}_{j}(z, Y_j). \tag{C.10}$$

Guessing a solution for the value function and applying the method of undetermined coefficients, the value of the option of opening an affiliate in country j has general solution given by

$$V_j^o(z, Y_j) = A_j^o(z) Y_j^{\alpha_j} + B_j^o(z) Y_j^{\beta_j}. \tag{C.11}$$

As $Y_j \to 0$, the option of opening an affiliate becomes worthless, so it must be that $A_j^o(z) = 0$. Conversely, the option of opening an affiliate becomes more attractive as Y_j increases, so it must be that $B_j^o(z) > 0$.

Let Y_j^{OH} and Y_j^{HO} denote the thresholds for the realization of the composite shock that induce a firm to open or shut down an affiliate in country j, respectively. It is important to point out that, when a firm decides to open an affiliate in a country, it considers not only the value of its horizontal sales, but also the option value of potential exports to any destination country. For this reason, the value-matching and smooth-pasting conditions that deliver the parameters $A_j^h(z)$, $B_j^o(z)$, and the policy functions Y_j^{OH} and Y_j^{HO} entail tangency conditions linking the option value function $V_j^o(z, Y_j)$ and the total value of the affiliate $V_j^a(z, \mathbf{Y})$,

$$V_j^o(z, Y_j^{OH}) = V_j^a(z, Y_j^{OH}, \mathbf{Y}_{-j}) - F_j^h \quad , \quad V_j^o(z, Y_j^{HO}) = V_j^a(z, Y_j^{HO}, \mathbf{Y}_{-j}), \tag{C.12}$$

$$V'^o{}_j(z, Y_j^{OH}) = V'^a{}_j(z, Y_j^{OH}, \mathbf{Y}_{-j}) \quad , \quad V'^o{}_j(z, Y_j^{HO}, \mathbf{Y}_{-j}) = V'^a{}_j(z, Y_j^{HO}), \tag{C.13}$$

where , $\mathbf{Y}_{-j}$ denotes the vector of composite shocks in countries other than j.

C.2 Aggregation: price indexes

We now show how to solve for the vector of price indexes P_k, for $k = 1, ...N$, and for the laws of motion governing the evolution of affiliate operations over time across countries. As we only consider MNEs from the United States, we compute the price index as an aggregate of the prices associated with transactions of US MNEs and of domestic firms:

$$P_k^{1-\eta} = P_{kkk}^{1-\eta} + P_{US,kk}^{1-\eta} + \sum_{j \neq k} P_{US,jk}^{1-\eta}, \tag{C.14}$$

where P_{kkk} denotes the aggregate price of domestic varieties, $P_{US,kk}$ denotes the aggregate price of varieties produced via the horizontal operations of US affiliates in k, and $P_{US,jk}$ denotes the

aggregate price of varieties produced by US affiliates in j and exported to k:

$$P_{kkk}^{1-\eta} = \int_{\Omega_{kkk}} \left(\frac{\eta}{\eta-1}\frac{w_k}{z}\right)^{1-\eta} dG_k(z), \tag{C.15}$$

$$P_{US,kk}^{1-\eta} = \int_{\Omega_{US,kk}} \left(\frac{\eta}{\eta-1}\frac{w_k}{zZ}\right)^{1-\eta} dG_{US}(z), \tag{C.16}$$

$$P_{US,jk}^{1-\eta} = \int_{\Omega_{US,jk}} \left(\frac{\eta}{\eta-1}\frac{\tau_{jk}w_j}{zZ}\right)^{1-\eta} dG_{US}(z) \tag{C.17}$$

and Ω_{kkk}, $\Omega_{US,kk}$, $\Omega_{US,jk}$, denote the corresponding sets of varieties produced. $G_k(z)$ denotes the exogenous distribution of productivity of firms from country k.

The price indexes depend directly on the US productivity shock $Z = e^X$ and indirectly —via the integration sets— on the demand shocks Q_k. Moreover, as shown below, the integration sets themselves depend on the entry and exit thresholds, which in turn depend on the price indexes. To solve the aggregation problem, we appeal to the equivalence result shown in Leahy (1993): when solving the entry and exit problem, each firm takes aggregate prices and the sets of firms operating in each country as given, and does not take into account the effect of its own entry and exit decisions on these variables.

We assume that the mass of firms in each country k, M_k, is constant. The endogenous mass of affiliates of US firms located in j, $M_{US,j}$, is given by continuing plus new affiliates,

$$M'_{US,j} = M_{US,j} \cdot (1 - G_{US}(z_{US,j}^{HO})) + (M_{US} - M_{US,j}) \cdot (1 - G_{US}(z_{US,j}^{OH})), \tag{C.18}$$

where $z_{US,j}^{OH}$ ($z_{US,j}^{HO}$) is the productivity threshold that induces a US firm to open (shut down) an affiliate in j. Notice that $z_{US,j}^{OH}(Y_j)$ ($z_{US,j}^{HO}(Y_j)$) is the inverse of the threshold in the realization of the shock $Y_j^{OH}(z)$ ($Y_j^{HO}(z)$), whose existence is guaranteed by the monotonicity property of the thresholds shown in Proposition 1.

Similarly, the mass of affiliates of US firms located in j that export to k is given by continuing plus new exporters to k,

$$M'_{US,jk} = M_{US,jk} \cdot (1 - G_{US}(z_{US,jk}^{EO})) + (M_{US} - M_{US,jk}) \cdot (1 - G_{US}(z_{US,jk}^{OE})), \tag{C.19}$$

where $z_{US,jk}^{OE}$ ($z_{US,jk}^{EO}$) is the productivity threshold that induces an affiliate of a US firm in j to start (stop) exporting to k.

C.3 Proofs

In this section we prove Propositions 1 and 2. To this end, notice that, when $A_j^e(z) = A_{jk}^e(z) = 0$, the systems of value-matching and smooth pasting conditions (C.5)-(C.6) and (C.12)-(C.13) only identify the entry thresholds Y_j^{OH}, Y_{jk}^{OE} and can be solved in closed form, delivering the expressions in (22) and (23). Additionally, the option value parameters $B_j^o(z)$, $B_{jk}^o(z)$ can be characterized in closed form,

$$B_j^o(z) = \beta_j^{-\beta_j}(\beta_j - 1)^{\beta_j - 1} \cdot \left(\frac{f_j^h + \rho F_j^h}{\rho} - \mathbf{V}_j^E(z, \mathbf{Y}_{-j}) \right)^{1-\beta_j} \cdot \left(\frac{\kappa_{jj}(z)}{\rho - \tilde{\mu}_j} \right)^{\beta_j}, \quad \text{(C.20)}$$

$$B_{jk}^o(z) = \beta_k^{-\beta_k}(\beta_k - 1)^{\beta_k - 1} \cdot \left(\frac{f_{jk}^e + \rho F_{jk}^e}{\rho} \right)^{1-\beta_k} \cdot \left(\frac{\kappa_{jk}(z)}{\rho - \tilde{\mu}_k} \right)^{\beta_k}, \quad \text{(C.21)}$$

where $\kappa_{jk}(z) \equiv H(\tau_{jk} w_j / z)^{1-\eta} P_{jk} \lambda_{jk}$ and $\mathbf{V}_j^E(z, \mathbf{Y}_{-j}) = \sum_{k \in \mathcal{A}_j(z)} \left[\frac{\kappa_{jk}(z) Y_k}{\rho - \tilde{\mu}_k} - \frac{f_{jk}^e}{\rho} \right] + \sum_{k \notin \mathcal{A}_j(z)} \left[B_{jk}^o(z) Y_k^{\beta_k} \right]$.

Equations (C.20) and (C.21) reveal that the option value of opening an affiliate (exporting from an affiliate) is decreasing in both the fixed and sunk costs of affiliate opening (exporting). In addition, the option value of opening an affiliate is increasing in the value of the potential export network of the affiliate, highlighting the effects of the compound option mechanism. Finally, both the option values of opening and exporting from an affiliate are increasing in firm productivity z.

Proof of Proposition 1. Affiliate's variable profits and the value of an affiliate's export network are increasing in firm productivity,

$$\frac{\partial \kappa_{jk}(z)}{\partial z} > 0, \quad \text{(C.22)}$$

$$\frac{\partial \mathbf{V}_j^E(z, \mathbf{Y}_{-j})}{\partial z} > 0.. \quad \text{(C.23)}$$

Given (C.22) and (C.23), the proof for the affiliate export entry threshold is immediate,

$$\frac{\partial Y_{jk}^{OE}(z)}{\partial z} = \underbrace{\left(\frac{\beta_k}{\beta_k - 1} \right) \cdot \left(\frac{f_{jk}^e + \rho F_{jk}^e}{\rho} \right) \cdot (\rho - \tilde{\mu}_k)}_{\geq 0} \cdot \underbrace{\left(\frac{1}{-\kappa_{jk}(z)^2} \right)}_{<0} \cdot \underbrace{\frac{\partial \kappa_{jk}(z)}{\partial z}}_{>0} \leq 0.$$

For the affiliate opening threshold, we compute the derivative in the scenario in which (f_j^h +

$\rho F_j^h)/\rho - \mathbf{V}_j^E(z, \mathbf{Y}_{-j}) > 0$, so that $Y_j^{OH}(z) > 0$ and the entry problem is well-defined,

$$\frac{\partial Y_j^{OH}(z)}{\partial z} = \underbrace{\left(\frac{\beta_j}{\beta_j - 1}\right)}_{>0} \cdot \left\{ \underbrace{\frac{-\partial \mathbf{V}_j^E(z, \mathbf{Y}_{-j})}{\partial z} \cdot \frac{\rho - \tilde{\mu}_j}{\kappa_{jj}(z)}}_{<0} + \underbrace{\left(\frac{f_j^h + \rho F_j^h}{\rho} - \mathbf{V}_j^E(z, \mathbf{Y}_{-j})\right)}_{\geq 0} \cdot \underbrace{\left(\frac{\rho - \tilde{\mu}_j}{-\kappa_{jj}(z)^2}\right) \cdot \frac{\partial \kappa_{jj}(z)}{\partial z}}_{<0} \right\} \leq 0.$$

Proof of Proposition 2. Affiliate's variable profits are increasing in the taste shifter,

$$\frac{\partial \kappa_{jj}(z)}{\partial \lambda_{jj}} \quad > \quad 0. \tag{C.24}$$

Also for this proof we compute the derivative in the scenario in which $(f_j^h + \rho F_j^h)/\rho - \mathbf{V}_j^E(z, \mathbf{Y}_{-j}) > 0$, so that $Y_j^{OH}(z) > 0$ and the entry problem is well-defined. Given (C.24), the proof is immediate,

$$\frac{\partial Y_j^{OH}(z)}{\partial \lambda_{jj}} = \underbrace{\frac{\beta_j}{\beta_j - 1} \cdot \left(\frac{f_j^h + \rho F_j^h}{\rho} - \mathbf{V}_j^E(z, \mathbf{Y}_{-j})\right)}_{\geq 0} \cdot \underbrace{\left(\frac{\rho - \tilde{\mu}_j}{-\kappa_{jj}(z)^2}\right)}_{<0} \cdot \underbrace{\frac{\partial \kappa_{jj}(z)}{\partial \lambda_{jj}}}_{>0} \leq 0,$$

and

$$\frac{\partial Y_j^{OH}(z)}{\partial F_j^h} = \frac{\beta_j}{\beta_j - 1} \cdot \left(\frac{\rho - \tilde{\mu}_j}{\kappa_{jj}(z)}\right) > 0.$$

Mexico	0.114	0.088	0.021	0.032	0.026	0.038
Singapore	0.115	0.044	0.023	0.029	0.026	0.014
Average	0.113	0.083	0.025	0.042	0.027	0.037

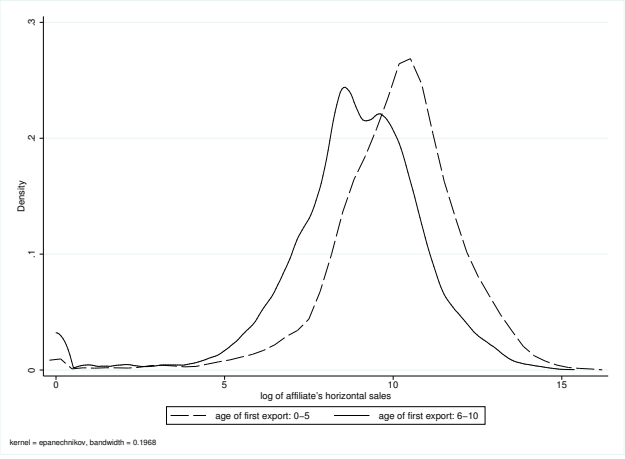

Note: MNEs shutting down affiliates in j are expressed as shares of the total number of affiliates in j in the period before exit. Affiliates that stop exporting are expressed as shares of the total number of affiliates in j that export in the period before entry. Calculations are conditional on affiliate entry. Averages across years.

Figure D.1: Exporter and early-exporter size advantage, OLS.

(a) Exporters vs non-exporters

(b) Early vs late exporters

Notes: Sample of new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. Kernel density of log horizontal sales for affiliates that: are born with exclusively horizontal sales (non-exporters) and those with exports (exporters), in (D.1a); start exporting in their first five years of life and those that start after five years of life, in (D.1b).

Table D.9: First-affiliate size and cost advantage, OLS.

Dependent variable	probability of being the first affiliate of a MNE			
	(1)	(2)	(3)	(4)
Log of horizontal sales	0.013***	0.012***	0.012***	0.011***
	(0.003)	(0.003)	(0.003)	(0.003)
Number of business procedures		-0.006***		-0.008***
		(0.001)		(0.002)
Cost of starting business			-0.006***	-0.0004*
(% of GDP p.c.)			(0.0002)	(0.0002)
Obs	36,127	36,127	36,127	36,127
R-squared	0.291	0.295	0.293	0.297

Note: Observations at the affiliate-year level, for new majority-owned affiliates that survive for at least ten consecutive years, in manufacturing. The variables "Number of business procedures" and "Cost of starting a business" are from the World Bank's Doing Business dataset. All specifications include host country GDP (from Penn World Tables, 9.0), year fixed effects, and parent fixed effects. Standard errors, clustered at the parent level, are in parenthesis. Levels of significance are denoted $^{***}p < 0.01$, $^{**}p < 0.05$, and $^{*}p < 0.1$.

Table D.10: Calibrated MNE costs, as share of sales, by country.

	Sunk costs F_j^h (% of parent US sales)			Fixed costs f_j^h (% of horizontal sales)		
Sales percentiles	5th	50th	95th	5th	50th	95th
Brazil	0.189	0.068	0.007	16.25	9.960	1.530
