Getting through:
Communicating complex information

Michael McMahon,* Matthew Naylor†

March 2025

Abstract

Policymakers communicate complex messages to multiple audiences; we investigate how complexity impacts messages 'getting through' effectively. We distinguish 'semantic' complexity - the focus of existing empirical studies - from 'conceptual' complexity, which better reflects information-processing costs identified by theory. We conduct an information-provision experiment using central bank communications; *conceptual* complexity - captured by a novel measure we construct - matters more for getting through, even for economics-trained individuals. Yet, recent Bank of England efforts to simplify language reduced traditional *semantic* measures, but conceptual complexity has actually *increased*. Our findings can direct efforts for effective policy communication design.

Keywords: Information transmission, central bank communications, linguistic complexity, rational inattention

1 Introduction

Information transmission is typically difficult when messages are complex. In a world in which attention is a scarce resource, people allocate their attention to different sources of information by balancing the relative costs and benefits (Sims 1998, 2003, 2006). In such rational inattention environments, costs are typically thought of as information-processing costs. An established literature in information theory associates such costs with the 'mental effort' of processing *new* information conveyed by *specific* words (Shannon 1948, Hale 2001, Levy 2008). Empirical work has sought to quantify these costs by measuring the 'complexity' of text. But the nature of this complexity is seldom well defined (Gentzkow et al. 2017), and existing measures may not capture the 'true' processing costs identified by information theory. Yet, the design of effective communications requires that complex messages are communicated in a way that is accessible; that they 'get through'.

In this paper, we distinguish 'semantic' from 'conceptual' complexity. The primary aim is to understand the impediments to information transmission, by investigating individuals' capacity to process *complex* information. Our main contributions are to construct a novel measure of conceptual complexity – the Conceptual Complexity Index – and to use a large information provision experiment on a sample of the general public to show that it is *conceptual* complexity that matters far more than semantic complexity for 'getting through'.

Empirically, we develop a novel 'conceptual' complexity measure that captures the difficulty in comprehending a message arising from fundamentally not understanding certain words or how things are related. This differs from the existing narrow focus on texts' semantic structure, for example average word and sentence length (Bushee et al. 2018). These measures, such as the Flesch-Kincaid score,[1] do not capture the complexity of the *content* of the information itself and likely miss a principal information processing cost identified in the information-theory literature: *new* information from *specific* words. We show in our experiment that this is the case — it is conceptual complexity that matters. This finding provides important direction for the design of more effective policy communication.

The environment that we explore is central banking. Central banks, like other policymakers and possibly more so, have to communicate complex messages to different audiences with different degrees of informedness. For instance, they must communicate to financial markets as well as, increasingly, to the general public. The importance of effective communication has grown in recent years, as communication has become a key tool in the central bank policy shed. Evidence indicates that, in relation to financial markets, central bank messages broadly get through. Coibion et al. (2022) and Swanson (2018) amongst others document that communications have been largely successful in shaping expectations for inflation and interest rates, as intended, amongst financial market participants. However, in relation to broader audiences, they are less successful. A wealth of evidence documents that household and firm inflation expectations are consistently far above central bank targets, highly dispersed across individuals, and volatile in the time series (D'Acunto et al. 2022). Yet, a growing body of research emphasises that their expectations matter just as much as, if not more than, those of financial market participants

[1]The Flesch-Kincaid score is a widely used measure of 'readability' developed by a combination of Flesch (1948) and Kincaid et al. (1975). It provides an estimate of the number of years of education an individual would need to have, on average, to be able to understand a piece of text.

for the transmission of monetary policy (Reis 2023, D'Acunto, Hoang & Weber 2020, Malmendier & Nagel 2016, Bachmann et al. 2015, Armantier et al. 2016). After all, firms set prices and wages, and household consumption is the largest component of GDP in most advanced economies (Beraja et al. 2019, Agarwal & Qian 2014).

So, why aren't central bank messages getting through to these broader audiences? One reason is that the *costs* of paying attention to often very complex central bank communications are high. This is what we focus on in this paper. A growing body of research, led by Haldane & McMahon (2018) and Coibion et al. (2022), emphasises the merits of simplifying communications. However, our understanding of what linguistic complexity *is*, let alone the role it plays in generating barriers to paying attention to central bank communications, accurately processing information, and developing well-anchored expectations, remains limited. D'Acunto et al. (2022) describe the challenge of understanding how policy communication can influence consumer beliefs and choices as an important open area for research.

Another reason for low attention is that the *benefits* to paying attention may be small. This may contribute to inattention in low inflation economies where it is of little consequence whether inflation will be 1.5% or 2% in two year's time (Sims 2015). In our experiment, we abstract from differences in the perceived benefits of attention; these should be randomly allocated across the treatments allowing us to compare the impact of text-complexity on attention. We conducted our main experiment while inflation was still around target levels after the Covid-19 pandemic. Nonetheless, while the benefits of attention to inflation developments has likely increased in the recent inflationary period, there is still evidence of inattention in both the UK and US.[2]

Our primary contribution is to distinguish between 'semantic' and 'conceptual' dimensions of complexity; constructing a novel quantitative measure of conceptual complexity that is distinct from existing measures of semantic complexity. This measure, the Conceptual Complexity Index (CCI), utilises a dictionary of economic and financial jargon terms, to capture the quantity and breadth of jargon used in a text, as well as the range of different technical topics covered. It is this measure, and not more standard measures of semantic complexity, that captures variation in complexity on information processing and gives rise to the impact that we show in the experiment. Though our design and choice of jargon words is specific to the central banking environment we study, the idea could be adapted to any communication environment. We hope that it can broaden future empirical analyses of the two different types of linguistic complexity, and in particular, proves useful in other fields in which linguistic complexity has been measured, including public economics (Benzarti & Wallossek 2023), regulatory economics (Katz & Bommarito 2014, Ash 2015, Li et al. 2015) and corporate reporting (Loughran & McDonald 2016, Leuz & Wysocki 2016, Hoberg et al. 2014, Chen et al. 2014, Engelberg et al. 2012, Garcia 2013, Da et al. 2014, Buehlmaier & Whited 2018).

[2]UK survey data shows that, despite interest rate increases that policymakers expect will return inflation toward target, household inflation expectations have *remained* largely unanchored in the high inflationary environment since 2022. The August 2022 Inflation Attitudes Survey found that fewer than 20% of the UK public expect inflation to be at the BoE's 2% target rate in 5-years time. This contrasts with long-run (3-year) inflation expectations amongst professional forecasters, which remained firmly anchored with mean 1.9% (Survey of Professional Forecasters). There is similar evidence in the US. In the US, 5-year ahead household inflation expectations rose to above 3% in June 2022 (Michigan Survey of Consumers), with significant disagreement across respondents (see Kansas City Fed Research).

As an example of its potential value, we apply the CCI, along with traditional measures of semantic complexity, to quarterly Bank of England (BoE) publications. We show that efforts to simplify language have been successful if one focuses only on semantic dimensions of complexity (e.g. the Flesch-Kincaid score). However, the conceptual complexity of its reports, as captured by the CCI, has not followed the same trend-decline. Instead, conceptual complexity has often *increased* over the same period for certain publications and demonstrated far greater volatility.

Our second contribution is to test the relative importance of semantic and conceptual complexity in an information provision experiment with 1,859 members of the public. We randomly assign respondents to hypothetical central bank reports that vary in complexity across semantic and conceptual dimensions. Controlling for demographic factors, we are able to identify the causal local average treatment effect of reading more complex texts on respondents' information processing capacity, as well as on factors likely to influence the relative costs and benefits people face of paying attention to central bank communications.

We find that *conceptual* complexity matters more than semantic. It reduces: (i) respondents' perceived understanding of the report they read, (ii) their actual understanding of the information conveyed, and (iii) their sentiments towards the central bank (such as trust). In contrast, semantic complexity has little to no effect. Moreover, we show evidence supporting the generalisability of these experimental results: each of these results hold focusing on a sub-sample of highly educated and technically trained respondents who studied economics at university; while conceptual complexity of BoE publications filters through to media articles reporting on them, which can remain highly complex and commonly report an imprecise signal of the original message. Taken together, our findings have potentially important implications for effective communications with a range of actors in the economy, not just the general public.

The measured impact of complexity on reducing respondents' understanding is consistent with the predictions of a simple rational inattention model we develop, based on Mackowiak & Wiederholt (2009), that embeds complexity of communications in an individual's optimal attention allocation decision. In this model, by construction, the cost of paying attention to central bank communications depends on the linguistic complexity of the message. In turn, complexity reduces the degree to which people are willing to pay attention to messages communicated by the central bank, and thus, the degree to which they form accurate beliefs about the economy and well-anchored expectations. While we model the cost of information processing as being unidimensional (as is typical in such models (Haldane et al. 2019)), the results from the experiment demonstrate that conceptual, not semantic, complexity give rise to differences in understanding and belief formation consistent with a 'true' cost.

Our work has important and clear implications for policy institutions such as central banks. In his first press conference as Governor of the Reserve Bank of New Zealand in 2018, Adrian Orr expressed that policymakers' challenge "is to speak in plain English as opposed to in a high-tech scientific language which only about half a dozen people understand and even less are interested in".[3] Our results show that for policy institutions to 'get through' to their broad audiences, they should pay close con-

[3]As quoted by Bloomberg in an article published in January 2019.

sideration to the complexity of the language they use. In particular, they should focus on broader dimensions of complexity than those captured by the restrictive measures used by both the research literature and policy institutions to date. Our results suggest that conceptual complexity is particularly important, not just in relation to people's understanding of information (on which most of the literature has focused, in relation to managing inflation expectations (Coibion et al. 2022)), but also people's sentiments (such as trust) towards the central bank. Our results also suggest that conceptual complexity matters not only for effective communications with the general public, but potentially also for *all* economic agents.

Our work is related to the growing literature on central bank (CB) communications. Initially, studies focused on transparency and the benefits of divulging more information. More recently, the literature has broadened as the role of communication has grown in the wake of the Financial Crisis and the adoption of Forward Guidance policies. Communication has become a fundamental part of CB policy, with general agreement on the importance of clear communications as a tool for anchoring expectations (Binder 2017, Woodford 2010, Bernanke 2003, Blinder et al. 2008). And considerable empirical evidence suggests that professional forecasters' expectations are indeed well anchored by CBs (Gürkaynak et al. 2007, Ball & Mazumder 2011, Beechey & Johannsen 2011, Davis 2014).

However, despite growing recognition that CBs have many different target audiences,[4] relatively little academic attention has concerned the expectations of the general public (Blinder (2009), Binder (2017), Haldane (2017), van der Cruijsen et al. (2010, 2015)). Haldane (2017) describes this as symbolising a "selective revolution" in terms of CB transparency. This has occurred despite the fact that a growing body of empirical evidence suggests that: (i) household expectations matter for activity and financial choices (Reis 2023, Bachmann et al. 2015, Malmendier & Nagel 2016); and (ii) most retailers, wholesalers, price- and wage- setters, form expectations in a way which closely resemble that of households, rather than that of professional forecasters (Blinder et al. 1998, Coibion & Gorodnichenko 2015, Nalewaik 2016).

Evidence to date suggests that CB communications are *not* getting through to the general public. Haldane & McMahon (2018) argue that public understanding of monetary policy has remained largely immune to the increased quantity of communication by CBs. Empirical evidence from the Netherlands (van der Cruijsen et al. 2010), US (Shiller 1997, Sapienza & Zingales 2013, Carvalho & Necchio 2015, Drager 2015), New Zealand (Kumar et al. 2015), South Africa (Marcus 2014), UK (Haldane & McMahon 2018), Japan (Bank of Japan, 2005), and Eurozone (European Commission, 2016) indicate low levels of informedness across both households and firms in relation to monetary policy. Binder (2017) finds that US household inflation expectations are far less anchored than are those of professional forecasters. Indeed, communicating effectively with the general public has proved so challenging that Blinder (2018) concludes that "central banks will keep trying but, for the most part, they will fail". Understanding why this may be is an open area of research (D'Acunto et al. 2022).

Our work seeks to glean insights into this puzzle, contributing to a nascent but growing empirical litera-

[4]The ECB (2002) noted: transparency is "more than simply releasing information; but it must be communicated to different audience across different environments". Bernanke (2003) outlines three Fed audiences: political authorities, financial markets and the general public. The Swedish Riksbank identifies eight (Dincer & Eichengreen 2009).

ture evaluating the role of linguistic complexity on the degree of attention paid to CB communications, using semantic modelling techniques (Born et al. 2014, Bholat et al. 2015, 2018, Chakraborty & Joseph 2017, Haldane 2017, Haldane & McMahon 2018, Hansen et al. 2018, 2019, Ferrara & Angina 2022, Mumtaz et al. 2023). Hernandez-Murillo & Shell (2014) estimate that an individual would require, on average, 19 years of schooling to understand FOMC minutes under the Yellen chairmanship. Bulir et al. (2012) similarly estimate that between 14-18 years of schooling would be required to understand CB publications in the UK, Chile, Czech Republic, Poland, and Sweden, and by the ECB. In contrast, the average number of years of schooling needed to understand a political speech is about 8, and a broadsheet newspaper 12 (Haldane & McMahon 2018). Indeed, experimental studies have found indicative evidence that the linguistic complexity of CB communications has significant negative effects on the degree of informedness (Coibion, Gorodnichenko & Kumar 2018, Coibion, Gorodnichenko & Ropele 2018, Humziker et al. 2018, Armantier et al. 2016, Armona et al. 2018, D'Acunto et al. 2018, Roth & Wohlfart 2018). On the back of this work, and consistent with advice by Sims (2015) that "there is an argument for guiding the simplification of the policy message", CBs have recently sought to reduce the complexity of their messages and communicate more effectively with the public.

However, the majority of studies to date have focused on restrictive measures of semantic complexity, such as the Flesch-Kincaid score (Mumtaz et al. 2023, Ferrara & Angina 2022). Some studies have sought to broaden focus to a wider variety of dimensions of complexity. Beyond the Flesch-Kincaid score, or simple word count measures, Amadxarif et al. (2019) use measures of 'conditionality' and 'lexical diversity', to reflect how cognitive loads may increase as individuals are required to consider a greater number of possible states of the world or have to interpret a greater range of words, respectively. However, these measures still do not capture the *content* of the text itself, which information-theoretic approaches show to be of central importance for the cognitive load of comprehending text. In particular, the information theory literature identifies the 'surprisal' of specific words – a theoretical measure of the extent to which a word came unexpected to a reader, as particularly key (Hale 2001, Levy 2008, Frank 2013).[5] We seek to operationalise these principles by developing a novel measure of 'conceptual' complexity, aimed at better capturing the 'true' costs of processing information.

Finally, a related, but separate strand of recent work, utilises Natural Language Processing (NLP) techniques to identify the specific topics discussed in text, model their relative importance within a text, and draw inferences on their association with information processing (Blei et al. 2012, Ludering & Winker 2016, Larsen & Thorsrud 2018, Hansen et al. 2018). And on-going work, has begun to focus on the role of narratives in reducing the costs of processing information (Shiller 2017, Ash et al. 2022, Flynn & Sastry 2022, Macaulay & Song 2023, McMahon & Rholes 2023). Narrative approaches, though in their infancy, potentially provide a complementary way to measure conceptual complexity.

The rest of this paper is structured as follows. In Section 2, we provide a theoretical argument for simplicity, by developing a simple rational inattention model of central bank communications. This model provides predictions about what we should expect to see if we vary the costs of attention. In Section 3, we construct our novel measure of conceptual complexity, and use this to analyse Bank of

[5]Recent (entropy-based) uncertainty reduction approaches to surprisal capture the degree to which a specific word informs an individual by the degree to which it reduces an individual's uncertainty about what is being communicated.

England publications. Section 4 details our experimental study, the results of which we present in Section 5. We discuss external validity in Section 6, and conclude in Section 7.

2 A Theoretical Argument for Simplicity

If the CB aims to align beliefs and expectations formed by economic actors more closely to CB forecasts and targets, communications are a potentially important tool. In this section, we formalise the argument for simplicity in communication by developing a simple rational inattention model, based on Mackowiak & Wiederholt (2009), that embeds complexity of communication in an individual's optimal attention allocation decision. In a world in which attention is a scarce resource, economic actors will decide how much (if any!) attention to pay to CB communications based on the relative costs and benefits of doing so (Sims 1998, 2003, 2006, 2010, Lamla & Lein 2006, Coibion, Gorodnichenko, Kumar & Pedemonte 2018).[6]

In the model, we focus on formalising the implications of complexity on the degree to which people choose to engage with messages communicated by the CB and, thus, process the information communicated. We show that linguistic complexity reduces the degree to which people pay attention to CB communications, which in turn reduces the accuracy of beliefs and expectations formed based on messages communicated by the CB.

There are two other possible channels through which complexity may also directly impact the accuracy of beliefs and expectations formed: (a) by *directly* reducing the degree to which people are able to accurately process information, for a given level of attention, and (b) by reducing trust in the central bank (found by Haldane et al. (2019) to be linked to reduced attention to CB communications, and Ehrmann (2024)). We do not formalise these additional channels for simplicity, but show empirical evidence of their existence in Section 5.

2.1 Model Environment

There are households and a central bank (CB). The CB is charged with minimising the impact of shocks on the economy. Its only tool for doing so is the anchoring of households' expectations to its long-run targets, through the publication of economic reports. We abstract from the direct use of other monetary policy tools, such as interest rate instruments or open market operations. We assume that the CB has perfect information about the state of the economy, while households are imperfectly informed. The CB transmits a message to households detailing the true state of the economy (containing both nowcasts and forecasts), and households optimally choose how much attention to pay to this message.

Households, which we assume to be homogenous and characterised by a representative household, h, maximise expected utility, subject to a constraint, by optimising the amount of attention they pay to

[6] In developing a simple theoretical model showing the importance of simplicity in central bank communications, we join an extensive list of work applying Sims' (2003) rational inattention framework to various economic settings such as optimal price setting (Mackowiak & Wiederholt 2009), consumption saving problems (Luo 2008), investment decisions (van Nieuwerburgh & Veldkamp 2009, Mondria 2010), settings with elements of price stickiness (Woodford 2009), stochastic choice settings (Matejka & McKay 2015), dynamic games (Myatt & Wallace 2012), global games (Yang 2015), dynamic learning (Steiner et al. 2017), and social learning (Caplin & Martin 2015).

the signal that they receive in the message transmitted by the CB. Household h's utility function is given by:

$$u_h(x, \tilde{x}_h) = -b(x - \tilde{x}_h)^2 \tag{1}$$

where x represents the true message communicated by the CB, $\tilde{x}_h$ represents household h's posterior belief, and $b > 0$ is the benefit derived from being well informed.[7] Deviations of $\tilde{x}_h$ from x reflect frictions caused by imperfect information which result in sub-optimal choices relative to the counterfactual case of perfect information, and a fall in household utility (Wiederholt 2010). A well-informed household has a smaller deviation of $\tilde{x}_h$ from x.

The constraint the household faces arises from the fact that attention is scarce and reflects the cost, c_h, associated with paying attention to the CB's message. Specifically, we follow Sims (2003) in modelling attention as an information flow and the constraint on attention is modelled as a bound on information flow. Household h's choice of how much attention to pay to the signal received via the message transmitted by the CB is characterised by their choice of how much information to process. The cost of paying attention is characterised by the cost of processing information. The cost is defined as:

$$c_h = \underbrace{(1 + \mu)}_{\text{marginal cost}} \cdot \underbrace{\lambda_h}_{\text{quantity}} \tag{2}$$

where μ is the linguistic complexity of the message communicated by the CB, and λ_h is the quantity of information that household h processes. The marginal cost of processing information is assumed to be increasing in the linguistic complexity of the CB's message.

2.2 Household Information Processing

Although the model is static, it is convenient to think of the transmission and receipt of the CB's message and the resulting impact on the household's updated beliefs as consisting of three stages.

Stage 1. Household h has a prior belief $\bar{x}_h$ about the state of the economy.

The household is uncertain about the true state of the economy, but knows the mean and variance of the distribution from which the state of the economy is drawn:[8]

$$x \sim \mathcal{N}(0, \sigma_x^2)$$

where σ_x^2 reflects uncertainty about the state of the economy. The household's prior belief will be (optimally) set equal to the expected state of the economy, such that: $\bar{x}_h = E[x] = 0$.

[7] We follow Sims (2003) in modelling utility as quadratic. This is a necessary condition for Gaussian uncertainty to be the optimal choice of distribution (Sims 2006). Sims (2006), Matejka & McKay (2015) and Steiner et al. (2017) consider more general utility functions.

[8] Sims (2003) explains that Gaussian uncertainty is optimal in this setting when agents face quadratic utility with a linear constraint. Sims (2006) and Mackowiak & Wiederholt (2009) corroborate this, finding that for low information flow (as is assumed in this setting), departures from Gaussianity are small with non-quadratic objective functions. In addition, Sims (2015) explains that RI models are easiest to handle and lead to particularly appealing and useful properties when random variables are normal.

Stage 2. The CB transmits a message, x, revealing the true state of the economy.[9]

Stage 3. Households receive a noisy signal depending on attention paid to the CB message:

$$s_h = x + \epsilon_h \tag{3}$$

where s_h is the signal received by household h, x is the true state of the economy as transmitted by the CB's message, and $\epsilon_h \sim \mathcal{N}(0, \sigma_\epsilon^2)$ is noise within the signal that is interpreted as arising from household h's limited attention.

Stage 4. The household updates its beliefs about the state of the economy.

Household h uses the noisy signal received from the CB to update its beliefs. Based on the utility function specified in equation (1), the utility maximising rationally inattentive household will choose to set their posterior belief, $\tilde{x}_h$, equal to the expectation of the true state of the economy as communicated by the CB's message, x, given the signal received, s_h. That is:

$$\tilde{x}_h = E[x|s_h] = \xi_h(x + \epsilon_h) \tag{4}$$

where ξ_h is the weight that household h attaches to the signal.[10]

The weight, ξ_h, that household h attaches to the signal, s_h, characterises the degree to which it pays attention to the signal received from the CB. The greater the weight attached to the signal, the more attention is paid, the closer is its conditional expectation of x given s_h (and, thus its posterior belief) to the true state of the economy. In contrast, the lower the weight attached to the signal, the less attention paid to the signal, the closer h's posterior belief lies to its prior.

2.3 Optimal Choice of Attention

In order to model the household's optimal choice of attention, we must relate the quantity of information processed by household h, λ_h (in equation 2), to the weight attached to the signal received from the CB, ξ_h (in equation 4). We follow much of the literature in doing this by modelling each as reflecting the expected reduction in uncertainty due to the acquisition of the signal. Information processed is captured by: $\lambda_h \equiv H(x) - E[H(x|s_h)]$; where $H(.)$ is a Shannon entropy function (Shannon 1948, Cover & Thomas 1991, Sims 2003, Mackowiak & Wiederholt 2009). Following Mackowiak, Matejka & Wiederholt (2018), we define the weight attached to the signal, ξ_h, as:

$$\xi_h \equiv \left(1 - \frac{\sigma_{x|s}^2}{\sigma_x^2}\right) \tag{5}$$

where $\xi_h \in [0, 1]$. A greater weight, ξ_h, attached to the signal, s_h, by household h results in a greater reduction in uncertainty given the acquisition of the signal. We can interpret $\xi_h = 1$ as reflecting

[9] We assume that the CB wants to anchor households' beliefs and expectations and so the CB will always seek to communicate all information about the state of the economy, with no incentives to withhold information or purposefully limit transparency (see Wiederholt (2020)).

[10] Equation 4 follows from the fact that $E[x|s_h] = (1 - \xi_h)\bar{x}_h + \xi_h s_h$ and $\bar{x}_h = E[x] = 0$

the scenario in which household h pays full attention to the signal and, thus, processes complete and perfect information about the state of the economy. In contrast, $\xi_h = 0$ reflects the scenario in which no attention is paid by household h to the signal and no information is processed.

By the Shannon entropy properties of a Gaussian variable, we can thus relate λ_h to ξ_h:

$$\lambda_h = \frac{1}{2} log \left(\frac{1}{1 - \xi_h} \right) \tag{6}$$

Households seek to maximise their expected utility subject to their constraint on attention:

$$\max \{E[u_h(x, \tilde{x}_h)] - c_h\} \tag{7}$$

which yields optimal weight:[11]

$$\xi_h^* = max \left(0, 1 - \frac{(1+\mu)}{2b\sigma_x^2} \right) \tag{8}$$

We can see that the optimal signal weight, reflecting the optimal level of attention, increases with the benefit of paying attention, b, and the degree of uncertainty surrounding the state of the economy, σ_x^2. In contrast, attention decreases with the linguistic complexity of the CB's message, μ.

The deviation of the posterior belief from the true message communicated by the CB is given by:[12]

$$x - \tilde{x}_h = \frac{(1+\mu)x}{2b\sigma_x^2} - \eta_h \tag{9}$$

where $\eta_h \equiv \xi_h^* \epsilon_h \sim \mathcal{N}(0, \sigma_\eta^2)$ can be interpreted as resulting noise in actions.[13]

In this setting, $(1+\mu) > 0$ results in *under-reaction* to messages from the CB, with households choosing a weight $\xi_h < 1$ and paying less attention to the message communicated by the CB than in a perfect information setting. The under-reaction to shocks is a standard implication in rational inattention settings.

This simple model produces a qualitative case for simplicity of CB communication. To the extent that linguistic complexity increases the perceived costs of paying attention, the deviation between expectations formed and the true message communicated by the CB (i.e. the 'inaccuracy' of expectations formed) is *increasing* in the degree of linguistic complexity: $\frac{\partial(x - \tilde{x}_h)}{\partial \mu} > 0$.

As mentioned already, we do not model an effect of complexity on trust in the CB and subsequently on expectations formation. We can think of trust as factoring (positively) into the perceived benefits to paying attention, b. We show that the deviation of expectations from the true CB message is strictly decreasing in the benefit to paying attention ($\frac{\partial(x - \tilde{x}_h)}{\partial b} < 0$). Thus, to the extent that complexity reduces trust in the CB, as Haldane et al. (2019) evidence, complexity would also be associated with lower

[11] Derivations are provided in Appendix A.1.

[12] Note that this deviation is zero in expectation by Law of Iterated Expectations.

[13] The variance of the noise in actions, $\sigma_\eta^2 = (\xi_h^*)^2 \sigma_\epsilon^2$ will be small as high attentiveness implies relatively high ξ_h^*, but relatively low σ_ϵ^2 and vice versa. At each extreme, $\sigma_\eta^2 = 0$ as $\sigma_\epsilon^2 = 0$ in the full attention case, whilst $\xi_h^* = 0$ in the no attention case.

levels of attention through its effect on trust. We also do not model the direct effect of complexity on information processing capacity for a given level of attention. This could be done by also incorporating μ directly in equation (9), exogenously from ξ_h.

One critique of this simple model is that, in the real world, most people do not pay any attention to CB communications and instead get their information about the state of the economy via the media, rather than directly from the CB (Lamla & Lein 2010, Lamla & Maag 2012, van der Cruijsen et al. 2010, 2015). In Appendix A.2, we describe an extension of the model to incorporate a role for the media. The key assumption is that journalists, j, are rationally inattentive and receive the CB signal before transmitting it on to final agents. We show that complexity may continue to impact the accuracy of expectations formed by economic actors, even when that information is first received, simplified, and then transmitted to those actors by highly trained journalists. The implication is that simplified communication may benefit financial market participants (who are likely to get their information directly from the CB) as well as journalists (who then transmit these messages to the broader public).[14] We provide evidence on this in Section 6.

.

While the model proposes a formal mechanism through which linguistic complexity affects public engagement with CB communications, we have not been explicit about what complexity is. That is, we have not distinguished between different dimensions of complexity. In fact, the main contribution of this paper is to explore the role that different types of complexity, 'semantic' and 'conceptual'. We turn now to being clear on that distinction.

3 Linguistic Complexity: Categories and Measurement

Complexity is seldom well defined (Gentzkow et al. 2017). The literature typically assumes that textual complexity increases "information processing costs", but generally offers little indication as to what these processing costs are (Amadxarif et al. 2019, Bushee et al. 2018). Within the field of CB communications, definitions of complexity have been particularly narrow and restrictive. Most empirical work has focused exclusively on a single measure of linguistic complexity: the Flesch-Kincaid (FK) score. In this section, we discuss the limitations of the FK score, propose a categorisation of linguistic complexity by 'semantic' and 'conceptual' dimensions, construct novel measures to capture the latter, and apply these measures to quarterly Bank of England publications.

3.1 Beyond the Flesch-Kincaid Score

The FK score is an objective measure of 'readability'. It estimates the number of years of education an individual would need to have, on average, to be able to understand a piece of text. The FK accommodates cross-country (Bulir et al. 2012), cross-institution (Haldane & McMahon 2018), and temporal

[14] One further point to note is that, in this simple setup, we do not incorporate the possibility that reduced complexity might *over-simplify* the message, and reduce the CB's ability to communicate a message accurately. Haldane et al. (2019) model the CB's choice of simplicity as a trade-off between engaging audiences and being able to communicate all important information accurately. The purpose of the simple model we develop, however, is to provide a framework through which we might think about complexity impacting the degree of attention individuals pay to CB messages, and thus the degree to which their beliefs and expectations formed are well-anchored.

(Hernandez-Murillo & Shell 2014) comparisons. However, as a measure of linguistic complexity, it is restrictive, focusing only on semantic structure, and accounting only for average sentence and word length of a piece of text. Linguistic complexity is far broader than this.

Significant interest has been expressed in expanding our understanding of the breadth and nature of linguistic complexity. Andy Haldane (2017), during his time as Chief Economist at the BoE, argued for a shift of focus towards behavioural aspects of information processing. He calls for more investigation on how the use of narratives and the expression of concepts, using terms with which readers can relate, might facilitate the processing of information and enhance engagement by wider audiences. Akerlof & Shiller (2009) and Shiller (2017) point to the use of "popular narratives" in other fields: marketing (Escalas 2007), journalism (Machill et al. 2007), education (McQuiggan et al. 2008), health interventions (Slater et al. 2003), and philanthropy (Weber et al. 2006). Despite this, relatively few studies within the field of CB communications have yet extended semantic modelling techniques to analyse measures of complexity beyond the FK score.

Our aim is to extend analysis in this field by developing a broader range of measures of linguistic complexity.

3.2 Categories of linguistic complexity

A number of taxonomies have been proposed to distinguish between forms of complexity. Amadxarif et al. (2019), following Colliard & Georg (2018), distinguish between 'local' and 'global' complexity. Within the context of CB regulations, local complexity refers to difficulties in processing the language of individual provisions, whilst global complexity refers to the network of inter-linked and cross-referenced provisions. Given that CB communications are relatively self-contained (comprehension does not rely on references to other documents).[15] We restrict analysis to 'local' complexity, and from hereon refer to 'linguistic complexity' as synonymous with 'local' complexity. We further distinguish between two forms of linguistic complexity: 'semantic' and 'conceptual' linguistic complexity. Whilst the former captures the grammatical and semantic structure of a piece of text, the latter instead is determined by the complexity of the content of the text.

Semantic and conceptual forms of complexity capture very different determinants of complexity and imply that different pieces of text can be rendered linguistically complex for different reasons. A document that discusses high level quantum mechanics using very short words and phrases would be regarded as relatively simple by a measure of semantic complexity, yet, in reality, it is so conceptually complex and technical that it is likely incomprehensible for most people.

Beyond the fact that conceptual complexity, intuitively, should be important, our motivation for focusing on it is rooted in an established literature on information-theory. Hale (2001) and Levy (2008) show that information processing costs are associated with the cognitive load, or new information, conveyed by specific words. In particular, they demonstrating that a crucial determinant of a word's information content is its 'surprisal' - a theoretical measure of the extent to which a word came as

[15] Of course, the macro economy more broadly is a complex web of interactions that underlie the MPR. Further research could extend measures of complexity to consider 'global' dimensions as well.

unexpected to a reader (Frank 2013). The novel measure of conceptual complexity that we construct in this section seeks to operationalise this concept within a single quantitative index.

In the following sections, we detail the existing measures of semantic complexity and construct a novel Conceptual Complexity Index (CCI), before applying these measures to quarterly BoE publications.

3.3 Measurement of linguistic complexity

3.3.1 Measures of semantic complexity

The two most common measures of 'semantic' complexity are the FK Score and Word Count.

Flesch-Kincaid (FK) Score

Introduced based on work by Flesch (1948) and Kincaid et al. (1975), the FK score offers a picture of the overall level of semantic complexity of text. It is computed as a composite measure of the average word and sentence length of a piece of text. The formula is given by:

$$\text{Flesch Kincaid Score} = 0.39\frac{n(Words)}{n(Sentences)} + 11.8\frac{n(Syllables)}{n(Words)} - 15.59$$

where $n(Words)$ refers to the total number of words in a piece of text. Analogous definitions hold for $n(Sentences)$ and $n(Syllables)$.

Word Count

Word Count provides a measure of the length of a piece of text(Szmrecsanyi 2004). Hernandez-Murillo & Shell (2014) compute the word count for Fed statements and show a substantial increase under the Yellen chairmanship. In contrast, Haldane (2017) explains recent BoE strategies to produce shorter forms of communications.

3.3.2 Novel measures of conceptual complexity

Empirical studies have shown that simpler terminology can dramatically increase the readability of text. For instance, Haldane (2017) explains that terms such as 'inflation', 'employment' and 'annuities' resonate less well with people than do their less technical counterparts, 'prices', 'jobs' and 'investment' (Smart 2016). Bholat et al. (2018) similarly emphasise the effect that technical jargon might have on the difficulty of understanding information. We address this in this section by constructing a novel measure of conceptual complexity with specific application to macroeconomics and finance.

Simple Measure: Proportion of Jargon (PoJ)

The simplest way to measure a document's conceptual complexity is to capture the number of technical jargon terms used in it. Very simply, the more densely packed a document is with jargon terms, the harder it is likely to be to understand. A simple measure of the proportion of jargon (PoJ) within a document, d, would be:

$$\text{PoJ}_d = \frac{\sum_{j=1}^{J} w_j}{\sum_{i=1}^{N} w_i} \equiv \frac{W_j}{W_i}$$

where w_j represents the number of instances that jargon term $j \in \{1, ..., J\}$ is mentioned, and w_i the number of instances that *any* word $i \in \{1, ..., N\}$ is mentioned. Thus, PoJ_d captures the total number of jargon words (W_j) as a fraction of the total number of words (W_i) in document d.[16] We apply this measure to BoE publications in Section 3.4, defining 'jargon' terms based on a dictionary that we construct by merging published economic, business, and financial A-Z lists.[17]

However, there are a number of features of conceptual complexity that this simple PoJ measure is unable to capture. For instance, it does not reveal whether a document refers to lots of different jargon words, or simply the same ones repeatedly. A document in which 10% of the words are a single jargon term (e.g. 'growth') is likely to be less complex than a document in which 10% of words refer to different jargon terms (e.g. 'growth', 'GDP', 'activity', 'output'). Furthermore, if different jargon terms are mentioned, this simple measure does not reveal whether they refer to similar concepts or completely distinct topics. The abovelisted jargon terms each relate to a similar concept, but a document that also discusses a greater range of topics, such as monetary policy, inflation, growth, financial markets, etc. is likely to be more conceptually complex.

We construct a more comprehensive measure of conceptual complexity, which we term the Conceptual Complexity Index (CCI), that seeks to capture each of these characteristics.

Conceptual Complexity Index (CCI)
The CCI has three key features. It increases in:

1. the proportion of jargon used;
2. the breadth and dispersion of *distinct* jargon terms used *within* a given topic;
3. the number of topics covered.

Feature 1. We use the simple PoJ_d measure described above as the baseline for feature 1. We then augment this measure by incorporating features 2 and 3 in a manner that ensures the CCI is still comparable to the simple PoJ_d measure above.

We consider that there are T broad topics relating to the economy. Each jargon term or phrase, j, is mapped to a topic $t \in \{1, ..., T\}$.[18] It is not the case that the words have to be synonyms within the topic; a piece carefully distinguishing between the level and rate of change of prices should appropriately use separate price and inflation terms. Rather, we consider a document that distinguishes between these first and second derivatives to be more conceptually complex than one that just makes

[16] We drop the subscript d from the right-hand side of the equation throughout this section for notational simplicity.
[17] Sources: Economist, the Guardian and Investopedia. A list of the terms included in this dictionary is provided in Appendix B.1, along with a more detailed discussion of the methods used.
[18] We detail this mapping in Appendix B.1.

reference to one.

Feature 2. We measure the within-topic intensity of jargon using a version of the Herfindahl index of concentration. We create a weight, ψ, that adjusts the jargon count within topic t (in document d) based on the 'concentration' (or, conversely, breadth and dispersion) of *distinct* jargon terms used within that topic.[19] This weight is given by:

$$\psi_{t,d} = \sqrt{\sum_{j_t=1}^{J_t} s_{j,t}^2}$$

where $s_{j,t} \equiv \frac{w_{j,t}}{W_{j,t}}$ represents the share of references, $w_{j,t}$, to jargon term $j_t \in \{1, ..., J_t\}$ in topic t in the total count of references to *all* jargon terms, $W_{j,t} \equiv \sum_{j_t=1}^{J_t} w_{j,t}$, in that topic. The weight, $\psi_{t,d} \in [0, 1]$ is equal to 1 if only a single jargon term j_t is used within topic t. It falls towards zero as more jargon terms within the topic are used, and specifically they are used in a less concentrated (or, equivalently, more dispersed) manner. The weight also treats differentially the use of alternative jargon terms once versus many times, reflecting the diminishing impact on conceptual complexity of using the same jargon term multiple times.

We then use a transformation of this weight, reflecting the 'concentration' of jargon terms, to scale the within-topic t jargon count as follows:

$$W_{j,t,d}^* = \frac{W_{j,t}}{\Psi_t}$$

where $\Psi_t = 2^{log_{10}\psi_t}$. This transformation is chosen such that where $\psi_t = 1$ it is also the case that $\Psi_t = 1$ and the adjusted jargon count $W_{j,t,d}^*$ in topic t is equal to the baseline jargon count $W_{j,t,d}$. As ψ_t decreases, the jargon count is adjusted upwards to reflect the greater conceptual complexity arising from a lower within-topic concentration (or, equivalently, greater breadth and dispersion) of jargon terms. Specifically, as ψ_t reduces by a factor of 10, the transformation is such that Ψ_t reduces by a factor of 2, thereby doubling the within-topic conceptual complexity.[20]

Feature 3. We draw inspiration from the tf-idf (term frequency - inverse document frequency) weighting commonly used in natural language processing, to account for the number of different topics discussed in document d. The 'topic-coverage' weight is given by:

$$\Phi_d = \frac{\log_{10}(T + v)}{\log_{10}(T + v) - \log_{10} T_d}$$

where T is the total number of topics that we distinguish between, T_d is the number of topics covered in the particular document d, and v is a coefficient that allows the user to adjust how extra topic coverage is penalised in the weighting. As detailed in Appendix B, we distinguish between 10 topics in total: monetary policy; inflation; output, production, and supply side; private demand (consumption and investment); fiscal policy (including government expenditure); open economy; labour market; financial market; financial stability and macroprudential policy; and 'other'). We then choose $v = 90$

[19] Again, we drop the notation d from the RHS of the equation for notational simplicity.

[20] This transformation is helpful to avoid exponential increases in $W_{j,t,d}^*$ as $\psi_t \to 0$.

such that covering all topics doubles the difficulty and, hence, the adjusted jargon count compared to a baseline of covering only one topic.[21]

Taking all of these adjustments into account, the Conceptual Complexity Index (CCI) is given by:

$$\text{CCI}_d = \frac{\left(\sum_{t=1}^{T} W^*_{j,t,d}\right) \times \Phi_d}{W_{i,d}}$$

That is, the CCI for a document d is increasing in the sum of the jargon counts (feature 1), across all topics $t_d \in \{1, ..., T_d\}$ covered in d, adjusted for the breadth and dispersion of *distinct* jargon terms within each topic t, $W^*_{j,t,d}$ (feature 2), and the range of topics covered, given by the topic-coverage weight Φ_d (feature 3). The index is then given as a proportion of the total number of words in the document W_i. $\text{CCI}_d = \text{PoJ}_d$ if document d refers only to a single jargon term in a single topic. Otherwise, $\text{CCI}_d > \text{PoJ}_d$ and this difference is increasing the breadth and dispersion of jargon terms used within each topic discussed, and the number of topics of topics covered in document d.

3.4 Application: Complexity of Bank of England publications

CBs communicate in a variety of forms, from press conferences and speeches to quarterly publications. In the UK, the Bank of England (BoE) releases three quarterly publications on monetary policy and economic conditions: the Monetary Policy Report (MPR, formerly 'Inflation Report'), the Monetary Policy Summary (MPS), and the Visual Summary (VS). The MPR, introduced in 1993, is the primary publication, detailing the state of the economy and monetary policy decisions. The MPS is a brief, but technical, summary of the MPR. The VS is a recent innovation, introduced in 2017 Q4, with the objective of conveying communications more simply and targeting broader audiences.[22]

In this section, we apply the complexity measures described and constructed in Section 3.3 to text from the three abovementioned quarterly BoE publications.[23] In order to do so, we first construct a text mining algorithm to generate a novel set of cleaned text data for each of these publications between Q3 2015 and Q3 2023, and combine this with MPR text data mined and shared with us by Hansen et al. (2019) to produce a dataset with text for 71 MPRs (Q4 2005 - Q3 2023), 37 MP Summaries (Q3 2015 - Q3 2023), and 28 Visual Summaries (Q4 2017 - Q3 2023). The mining of this data and construction of this dataset is no simple task and a useful contribution in and of itself.[24]

We show that, consistent with (i) active BoE efforts to simplify its communications; and (ii) the literature's focus on traditional measures of complexity such as the Flesch-Kincaid score, *semantic*

[21] Setting $v = 990$ would mean that covering all topics adds 50% to the adjusted jargon count.

[22] See Appendix B.2 for examples of each publication.

[23] That is, for the purpose of this paper, we do not investigate the complexity of other forms of BoE communications such as speeches from MPC members, transcripts from press conferences, or published minutes. However, the measures we construct would be easily applicable also to these forms of communication. Additionally, these measures could be applied to communications from other (english-speaking) central banks, such as the Fed or ECB. Applying our measures to broader ranges of central bank communications would be valuable contributions for future research.

[24] Details of the steps taken to do so are provided in Appendix B.2, and we intend to make this text mining and cleaning algorithm, which is replicable for future BoE publications releases, public on the CCI project website, for use in future research.

complexity has followed a clear trend-decline since the early 2010s. However, we show that, in contrast, dimensions of *conceptual* complexity, as captured by our novel measures, have *not* followed the same trend. They have evolved with much greater volatility, in particular for the MPR and MPS, and have, if anything, *increased* over this same period.

3.4.1 Semantic complexity

The varying aims and objectives of CB communications over time are well reflected in the semantic complexity measures of BoE publications, particularly the FK score. Since the 1990s, the BoE (like many other CBs) has sought to increase its transparency and placed greater weight on communications. This is reflected by the increasing length of MPR publications between 2005 and 2014 (Figure 1ai), rising from 16,350 words in Q1 2006 to 23,587 words in Q1 2014. Contemporaneously, Figure 1aii shows that the FK score also increased consistently during this period, estimating that an individual would require, on average, approximately 15 years of schooling to be able to understand the MPRs published in 2013, up from 12 years in 2005. Hence, not only did the length of MPR publications increase, but so did the semantic and structural complexity more generally.[25]

Around the early/mid 2010s, CBs began seeking to reduce the complexity of their communications in order to engage with broader audiences. This was an explicit objective of the BoE following the appointment of Mark Carney as Governor in 2013. It implemented the 'Vision 2020 strategy' which, in part, aimed to increase accessibility of communications, culminating in the introduction of the Visual Summary (VS). Indeed, these efforts are depicted clearly in Figures 1ai and 1aii, with a reversal of the trend increase across both semantic complexity measures. The length of the MPR fell to below 16,000 words in 2019, and, by the FK score, an individual required fewer than 10 years of schooling to understand the Q1 2020 MPR.

Most recently, following a sequence of significant macroeconomic shocks, we see sharp spikes in the length of the MPR (in Q2 and Q3 of 2020, after the onset of Covid-19 during which time the BoE published joint Monetary Policy and Financial Stability reports, and Q4 2021, after UK inflation had risen above the BoE's 2% target for the first time in nearly a decade), and a higher baseline length of the text, likely reflecting the broader macroeconomic uncertainty. Yet, despite this, the FK score remains relatively stable and low (hovering at around 12 since 2021), reflecting again the BoE's efforts to maintain lower levels of (semantic) complexity.

Finally, on the other two shorter publications, the VS has a significantly lower FK score (mean of 6.30), reflecting its aim of being more accessible, while the MPS is even more complex, by the FK metric, than the MPR (though this too has followed an, albeit more modest, downward trend).[26]

Taken together, focusing only on these measures of complexity, as much of the literature has generally done, one might conclude that efforts by the BoE to simplify its communications have been broadly successful. However, as we show below, the story is somewhat different across other dimensions of complexity.

[25] Summary statistics are presented in Table B.1 in Appendix B.2.3.

[26] These observations are consistent with previous analyses (Haldane & McMahon 2018)

3.4.2 Conceptual complexity

Moving on from measures of *semantic* complexity, Figures 1bi and 1bii show the evolution of *conceptual* complexity, as captured by our two novel measures: the Proportion of Jargon (PoJ) and the Conceptual Complexity Index (CCI). There are a few things to note.

First, and perhaps most importantly, we do *not* observe the same trend-decline in complexity since the early/mid 2010s across either metric as we saw for the semantic complexity measures. Since 2013, the MPR has maintained its PoJ (i.e. proportion of words that are jargon) consistently around 5%-6%. Its CCI (i.e. adjusting the PoJ to account for the breadth of jargon terms used and range of topics discussed), has fluctuated a little over the years, but has not exhibited the same trend-decline observed for the FK score. In contrast, its CCI significantly *higher* in recent periods (around 20%) than it had been in 2013 (around 13%). The MPS has also fluctuated significantly across both metrics, with again no clear trend-decline and significantly higher levels of complexity in more recent periods (over 25%) than in 2015 (when it was closer to 20%). Finally, the VS has also fluctuated (increasing between 2017 and 2021, before falling more recently), but again this hasn't followed the trend-decline observed with the FK score, and remains more complex than when it was first introduced.

Second, we observe the value of exploiting the additional information that the more sophisticated CCI is able to make use of, both in comparing: the relative *levels* of the three texts; and their relative *volatility*. In relation to the levels, focusing first on the simple PoJ measure in Figure 1bi, we see that, although the MPS typically has a higher score than each of the MPR and the VS, there have been periods in which the VS is similarly as complex as the MPS, and is consistently as, or more, complex than the MPR. Using only this simple metric, one might conclude that this is a rather concerning observation for the VS, which has been introduced specifically with the aim of engaging broader audiences. However, Figure 1bii shows us that, once we adjust the simple PoJ measure to take into account the range of topics that these reports cover, and the breadth of jargon used within these topics, encouragingly, the VS is indeed less complex than each of the other publications. Its CCI hovers around the 10% mark, while the adjustment for each of the MPR and MPS reports is much greater. Indeed, the CCI for the MPS peaked at 34% in 2018, and more recently lies around 25%, while the MPR lies around 20%.

In relation to the volatility, we see that, across both metrics, while the MPS is highly volatile, the MPR is more stable, perhaps partly due to its greater length. In contrast to each, the PoJ and the CCI each tell *different* stories for the volatility of the VS. While the PoJ metric depicts a rather volatile picture, the CCI presents a more stable one. This tells us that, while the proportion of words that are jargon in the VS fluctuates significantly, the range of jargon terms used and the topics discussed does not.

Figure B.7 in Appendix B.2.4 depicts the observations made above on the relative levels and volatility of the respective publications. Figures B.7ai and B.7aii depict the greater breadth of jargon terms and topics discussed in the MPS relative to the VS. We see much a greater range of jargon terms used in the MPS (identified by the coloured words), both within the same topic (e.g. 'gdp', 'growth', and 'activity') as well as across topics (covering monetary policy, inflation, output, financial markets, open economy, labour market, etc.). In contrast, the VS uses a much narrower range of terms and covers far

fewer topics; talking mainly about 'interest rates' and 'inflation' (signified by the size of these terms).[27] Meanwhile, Figures B.7bi and B.7bii depicts the volatility of MPS reports, captured by the conceptual complexity measures; showing visible and significant differences in the quantity and range of jargon used in different reports (2019 Q4 vs 2023 Q2).[28]

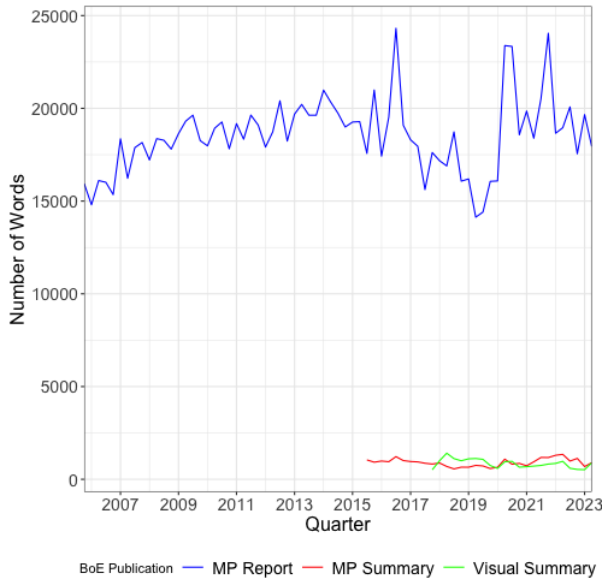

A final point worth noting is that, unlike the simple PoJ metric, the CCI seems to capture periods of heightened uncertainty, particularly in the MPR. The index captures visible peaks after the GFC between 2009 and 2010, as well as around the Brexit referendum in 2016 Q3. This potentially reflects the fact that, in seeking to communicate this heightened uncertainty, CBs tend to cover a broader *range* of topics, and use a greater *breadth* of jargon terms; rather than necessarily using *more* jargon.

To summarise, we see that active efforts by the BoE to simplify its communications have been largely successful if we focus (as much empirical work in this field has done) exclusively on *semantic* dimensions of complexity: both Word Count and the Flesch-Kincaid Score have systematically fallen across BoE publications. However, we do *not* see the same trend-declines across measures of *conceptual* complexity. In fact, we see both much greater volatility in these dimensions as well as, in particular for the MPR and MPS, complexity having *increased* across this dimension.

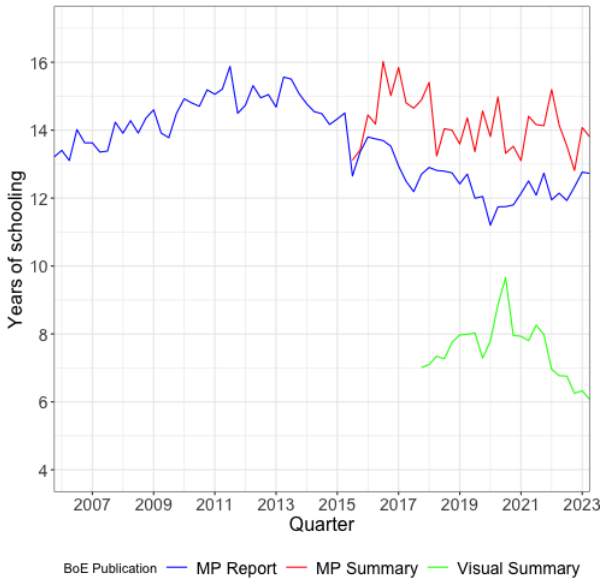

These observations motivate the following question: which dimensions of complexity matter *more*? This is what we seek to answer in the next section.

Figure 1a: Traditional Semantic Complexity Measures

(i) Word Count

(ii) Flesch-Kincaid Score

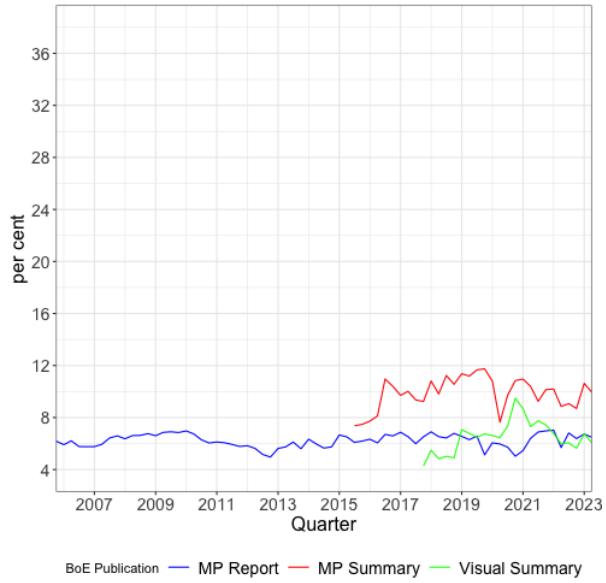

[27] Figures B.7ai and B.7aii also depicts the greater range of words (not just jargon) used in the MPS relative to the VS, by the size of the cloud itself. The greater the cloud, the greater the number of different words used.

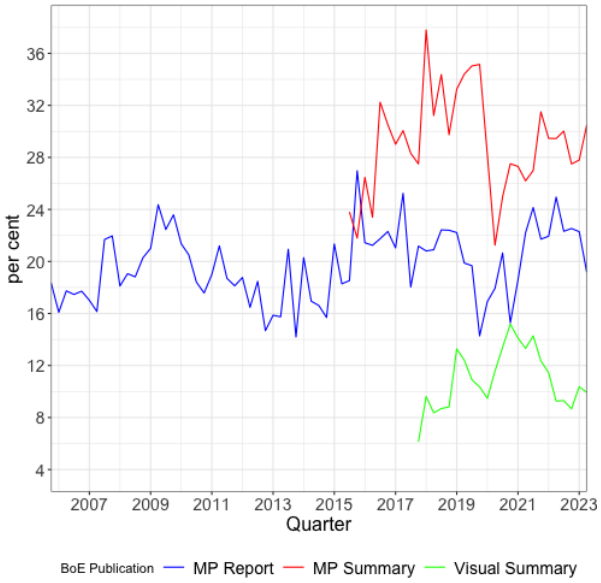

[28] We also provide the word cloud for the MPR across the entire sample period (2005-2023) in Figure B.6 of Appendix B.2.4.

4 Experimental Study

We run an experimental study to test which dimensions of complexity are most important for effective communication. The study is run through a survey company called 'Prolific', where participants are subscribed members who receive a certain amount of money per survey that they complete. We first ask participants a set of baseline questions relating to their demographic characteristics, level of informedness about the UK economy, and attitudes towards public institutions. We then randomly assign participants to one of six information treatments, which each consist of reading a report from a hypothetical central bank. The reports communicate the same underlying information, but vary in their degree of complexity across semantic and conceptual dimensions, with texts categorised as either 'Low', 'Medium', or 'High' complexity across each. Having received the information treatment, we test respondents' (i) *perceived* understanding of the report they read, (ii) *actual* understanding, and (iii) sentiments towards the central bank. The survey consists of 35 questions in total, and had a median response time of around 16 minutes.[29] Prolific provide data only on participants who completed the survey, so we cannot calculate attrition or compliance rates ourselves. However, they confirm that attrition rates were uncorrelated with the treatments provided. This section details the survey design, information treatments, and elicitation of beliefs. We discuss the external validity of our experimental findings in Section 6.

4.1 Representative sample

Our study consists of 1,859 representative members of the UK public and was conducted in June 2021. We ask participants a set of pre-treatment questions to both elicit prior beliefs as well as to test the representativeness of the sample. In particular, we elicit information on respondents' demographic

[29]The full survey is provided in Appendix X.

characteristics (such as age, income, occupation, level of education, and country of birth), as well as on their level of interest in economic affairs (such as whether they keep up with the state of the economy, or follow news about the Bank of England), their level of informedness about the economy (such as their priors for both the UK's current and historical levels of GDP, inflation, and interest rates), and attitudes towards public institutions (such as trust in the government, the legal system, and the Bank of England).

Comparing the demographic characteristics of our sample with official UK population statistics from the Office for National Statistics' 2021 census, we confirm that our sample is broadly representative.[30] We also compare the distribution of pre-treatment priors within our sample to those documented in other survey data. In particular, we gauge participants' understanding of macroeconomics and monetary policy by asking respondents which UK authority sets interest rates and what that authority's inflation target is. Consistent with survey evidence in the US by Coibion et al. (2022), we observe significant inattention amongst survey participants in relation to each, reported in Table C.1 of Appendix C. Only 60% of respondents answered that the 'Bank of England' or 'Monetary Policy Committee' set interest rates in the UK. On the inflation target, as in Coibion et al. (2022), the median response across the population was 3%, but with significant disagreement amongst respondents, represented by a significantly higher mean of 6.66%.[31] We also observe cross-sectional features that are consistent with documented evidence, with male, higher income, and more educated respondents reporting lower inflation targets on average, consistent with Coibion et al. (2022), D'Acunto, Hoang, Paloviita & Weber (2020), Binder & Rodrigue (2018), and Bryan & Venkatu (2001). Taken together, these results replicate stylised facts identified in the literature, and support the representativeness and validity of our survey.[32]

4.2 Treatments

After respondents complete the pre-treatment questions, we randomly assign them to one of six information treatments.[33] We report summary statistics for demographic characteristics and pre-treatment priors across each treatment arm in Table C.2 of Appendix C, and confirm through balance tests reported in Table C.3 that there are no statistically significant differences in characteristics across the

[30] For instance, our sample has an average age of 37 (compared to 41 across the population), 70% are either employed or self-employed (compared to 75%), amongst which their average income lies approximately around £25,000 (compared to £32,000), 80% were born in the UK (compared to 84%), and they have an average of around 15 years of education (compared to 14). We have a slightly higher split of females in our sample (60%, rather than 52%), but show that gender does not significantly impact our results. One difference is that, amongst the people who went to university in our sample, a relatively high proportion studied economics (20% compared to 2% in the population). This indicates that our sample may be, on average, slightly more technically trained in economics specifically than the general population. However, we show that these individuals are evenly distributed across treatment arms, explicitly account for their technical training in our regression analysis, and show that results are very similar across groups of individuals that studied economics and those that did not.

[31] We calculate the mean by winsorizing the distribution to exclude the top 5% of responses, given a very long right-hand tail.

[32] We also document in Table C.1 that males, high income, and highly educated individuals report a greater degree of trust in the BoE, a greater degree of perceived understanding of its role, and a greater degree to which they keep up to date with the state of the economy.

[33] In the initial experimental design, we allocated respondents to eight different texts. However, three of these texts (1, 7, and 8) have the same degree of both semantic and conceptual complexity, so we group them together for the purposes of defining the 'information treatments'. Henceforth, we refer collectively to these three texts as Text 1, which we use as the baseline or 'control' group. We show in Table D.4 of Appendix D that results are very similar if instead we explicitly filter out the respondents from texts 7 and 8.

treatments.

Each treatment consists of reading a report from a hypothetical central bank. The reports communicate the same underlying information about the state of the economy, the economic outlook, and the monetary policy decision, but vary in their degree of complexity across semantic and conceptual dimensions. Texts are categorised as either 'Low', 'Medium', or 'High' complexity across each dimension, as summarised in Table 1a. On the semantic complexity side, all texts are approximately 900 words long, so variation is based only on the FK score. Our 'Low' semantic complexity texts are within an FK score range such that, in theory, 8th and 9th Grade students should be able to understand the information therein. The 'Medium' semantic complexity texts should be interpretable by 12th graders / College students, while the 'High' semantic complexity text should be interpretable by Graduates. On the conceptual complexity side, variation is based on different combinations of the novel measures we construct in Section 3: the (simple) PoJ; and the (more sophisticated) Conceptual Complexity Index (CCI). We do not propose a 'grading' system akin to the FK score but, broadly, the 'Medium' conceptual complexity texts have a PoJ and CCI scores that are twice those of the 'Low' conceptual complexity texts. The 'High' conceptual complexity texts have the same PoJ as the 'Medium' texts, but around twice as high a CCI, indicating that they contain a similar total number of jargon terms, but with greater breadth of different jargon terms and across a greater range of topics.[34] The respective FK, PoJ, and CCI scores of each respective category of complexity is summarised in Table 1b.

Table 1: Texts vary across different dimensions of complexity

(a) Variation in complexity

		Semantic		
		Low	Medium	High
Conceptual	Low	Text 1	Text 2	
	Medium	Text 3	Text 4	
	High		Text 5	Text 6

(b) Degree of complexity

Complexity	**Semantic**	**Conceptual**	
	FK	PoJ	CCI
Low	7.5	5	10
Medium	12	10	17
High	15	10	35

To construct the six reports, we use actual Bank of England quarterly publications as benchmark starting points. We then manually adjust the text to: replace all UK- and timing-specific context with that of a hypothetical setting in a hypothetical economy; and vary the degree of complexity of the reports across semantic and conceptual dimensions. Specifically, we use the respective 2018 Q1 Visual Summary and Monetary Policy Summary publications as our benchmarks. We choose these specific reports for two reasons. First, using reports published by the same institution in the same period increases the likelihood that the underlying sentiment of the information is the same across texts, and thus that the 'ceteris paribus' condition holds across texts as we vary the degree of complexity across them. Second, these two respective reports, conveniently, also represent the extremities of complexity

[34] We show that in the formulation of the survey texts this is mainly driven by ...

across both semantic and conceptual dimensions amongst the Bank of England publications in our sample period. That is, the 2018 Q1 VS is the least semantically and conceptually complex report in our sample, while the 2018 Q1 MPS is the most semantically and conceptually complex. This ensures that the variation in the degree of semantic and conceptual complexity across our six treatments remains within a relevant range, and that the semantic structure and conceptual content reflects that actually used by central banks. Text 1 is based on the same degree of complexity as the 2018 Q1 VS, which we refer to as 'Low' semantic and conceptual complexity. Text 2 is constructed by adjusting the semantic structure of the text so as to increase the degree of semantic complexity to 'Medium', while maintaining the same degree of conceptual complexity. 'Medium' semantic complexity reflects an FK score that lies between the most semantically complex VS (2020 Q3) and the least semantically complex MPS (2022 Q4). Text 3 is constructed by instead introducing technical jargon terms into the report so as to increase conceptual complexity to 'Medium', while maintaining 'Low' semantic complexity. 'Medium' conceptual complexity reflects a CCI that lies between the most conceptually complex VS (2020 Q4) and the least conceptually complex MPS (2020 Q2). Text 4 is constructed by increasing both semantic and conceptual complexity to 'Medium'. At the other extreme, Text 6 is constructed based on the same degree of complexity as the 2018 Q1 MPS, with 'High' semantic and conceptual complexity, while Text 5 is constructed by reducing the degree of semantic complexity to 'Medium', while maintaining 'High' conceptual complexity. We provide the reports in full in Appendix F.[35] However, to give a sense of what variation in the degree of complexity looks like within the reports, across each dimension, we provide excerpts from Texts 1, 2, 4 and 6 in Table 2 (underlining added).

[35]It is worth noting that Texts 4 and 5 look observationally quite different. This evident difference in complexity is captured by the CCI, which is twice as large for Text 5 as it is for Text 4. While future research could evaluate the effect of increasing the CCI more gradually, the observed difference in complexity is *not*, on the other hand, captured by the FK score, which calculates the semantic complexity of these texts as being identical. This highlights the importance of broadening our measures of complexity in order to be able to appropriately capture these clear differences in complexity across the texts. Moreover, it also highlights the value of the CCI specifically over and above a simple PoJ metric to capture conceptual complexity, as the latter also implies that Texts 4 and 5 are identical.

Table 2: Text Excerpts

Text	Description
Text 1 (SC Low, CC Low)	Over the past year, prices have been rising faster than wages. That means people have not been able to afford as much. We think that is changing. The share of people out of work is now at its lowest level since 1975. And there are a lot of job vacancies. This means that companies are having to compete hard with each other to recruit and retain workers. One way they do that is by offering higher wages – so we expect bigger pay rises over the next few years. We think that pay will rise faster than prices this year, easing the squeeze on living standards.
Text 2 (SC Med, CC Low)	Over the past year, prices have been rising faster than wages, meaning that people have not been able to afford as much. We think that is changing, with the share of people out of work now at its lowest level since 1975 as well as the fact that there are a lot of job vacancies. This means that companies are having to compete hard with each other to recruit and retain workers. One way they do that is by offering higher wages – so we expect bigger pay rises over the next few years. We think that pay will rise faster than prices this year, easing the squeeze on living standards.
Text 4 (SC Med, CC Med)	Over the past year, prices have been rising faster than wages, meaning that people have not been able to afford as much. We think that is changing, with unemployment now at its lowest level since 1975 as well as the fact that the labour market is tight. This means that firms are having to compete hard with each other to recruit and retain labour. One way they do that is by offering higher wages - so we expect bigger wage rises over the next few years. We think that wages will rise faster than prices this year, easing the squeeze on living standards.
Text 6 (SC High, CC High)	Household consumption growth is expected to remain relatively subdued, reflecting weak real income growth... The firming of shorter-term measures of wage growth in recent quarters, and a range of survey indicators that suggests pay growth will rise further in response to the tightening labour market, give increasing confidence that growth in wages and unit labour costs will pick up to target-consistent rates.

There are two points to note. First, we noted above that constructing our six treatments from benchmark BoE reports published in the same period increases the likelihood that the 'ceteris paribus' condition holds across the texts. However, we also note that manually adjusting the language between these texts so as to vary the degree of semantic and conceptual complexity may indirectly alter the psychological and social characteristics of the text. We seek to capture any such differences between the texts, and confirm in Section 5.3 that it is the differences in *complexity* specifically that explains the effects we find on respondents' understanding of the information provided. Second, we noted in Section 2 that the CCI makes an adjustment from the PoJ, based on both (a) the range of topics covered and (b) the breadth and dispersion of jargon terms within each topic. We do not test between the relative effects of these two adjustments in this study, but hope that future work could investigate the relative importance of these features in more detail. .

4.3 Post-treatment questions

Having read the report, we then seek to draw insights on the degree to which the complexity of the information that respondents were exposed to might have impacted their beliefs. First, we test the degree to which households understood the information about the hypothetical economy described by the report written by the hypothetical central bank. Specifically, we capture respondents' (i) *perceived* understanding of the report, based on self-reported responses, and (ii) their *actual* understanding of the information they read, based on direct questions about the economy described. The motivation for the latter is clear: this is a direct test of the impact of complexity on respondents' information-processing capabilities. The motivation for the former is households' perceived understanding is likely to influence how willing households might be to pay attention to central bank messages. That is, independent of whether households actually understand information, if they *believe* they do not or will not, then they are less likely to seek to engage with it. From the notation in Section 2, their perceived 'benefit' of paying attention is low.

Having tested respondents' understanding of the report, we then inform survey participants that the hypothetical economy described by the report is similar to the UK, and that the report they read is similar in style to the reports written by the Bank of England. We then test for the effects of different degrees of complexity on respondents' sentiments towards the Bank of England. The motivation is that, as with people's *perceived* understanding of the information, sentiments towards the institution are also likely to impact people's desire to pay attention to and engage with CB communications. Indeed, we both directly ask respondents about their willingness to engage with future BoE publications, as well as indirectly by asking, for instance, the degree to which they trust the BoE having read the report. In the design of the questions, we follow the recommendations of Roth & Wohlfart (2018) to reduce measurement error and experimenter demand effects.

5 Results

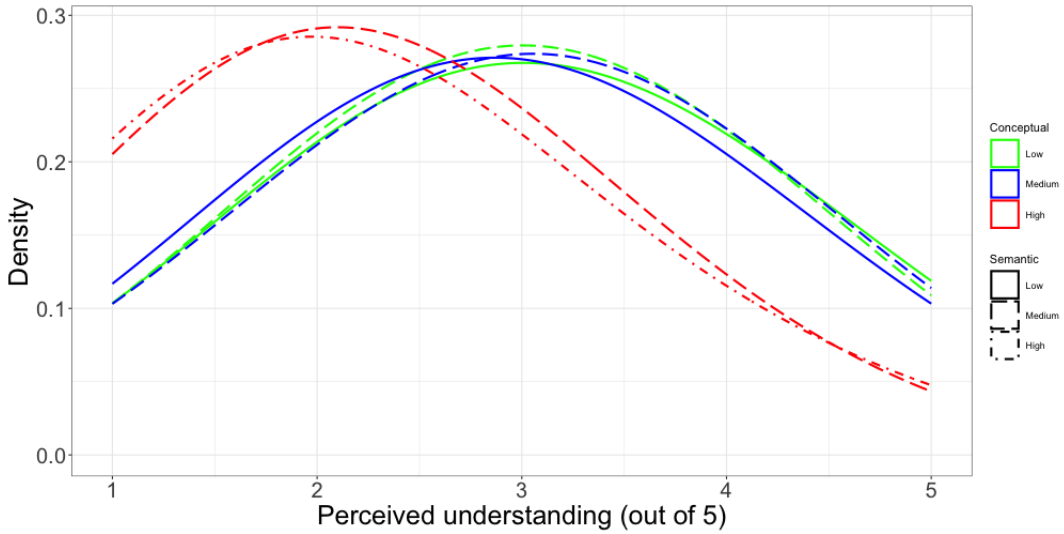

In this section, we test the causal effect of increasing complexity across conceptual and semantic dimensions on people's beliefs. We show that conceptual complexity matters significantly more than semantic complexity, significantly reducing (i) people's perceived understanding of information provided, (ii) their actual understanding of that information, and (iii) their sentiments towards the CB. In particular, we show that these effects occur over a certain threshold level conceptual complexity, exclusively captured by the CCI metric that we construct in Section 3. This threshold lies somewhere between the average degree of complexity of the BoE's Visual Summary and that of the Monetary Policy Summary. Moreover, we address a number of potential threats to the internal validity of our experiment, and outline the precautions we take to mitigate them.

5.1 Responses across treatments

We start by plotting the distribution of responses across each information treatment. We distinguish across the information treatments based on the degree of semantic and conceptual complexity of each text. The colour of each density plot reflects the degree of conceptual complexity of the text, with green reflecting 'Low', blue reflecting 'Medium', and red reflecting 'High' conceptual complexity. The line type of each density plot represents the degree of semantic complexity of the text, with solid lines

reflecting 'Low', dotted lines reflecting 'Medium', and dot-dash lines reflecting 'High' semantic complexity. Figure 2 plots the distribution of responses in relation to respondents' *perceived* understanding of the text they were randomly assigned to.

Figure 2: Density plot: Distribution of perceived understanding across treatments

Note: This figure presents the density distribution across treatments that vary in the degree of semantic and conceptual complexity, for responses to Q21: '*To what extent are you able to understand the content and messages of the material you just read?*', with options: (1) *None or nearly none of it*', (2) '*A small amount of it (less than half)*', (3) '*About half of it*', (4) '*A lot of it (more than half)*', '(5) *All or nearly all of it*'.

Comparing the distribution of responses across texts that vary in conceptual complexity, we see similar responses across texts of 'Low' and 'Medium' conceptual complexity, represented by the green and blue lines, respectively. Across these texts, the distributions are relatively normal and centered around the middle 'option' of 3 out of 5, reflecting that respondents perceived to have understood 'About half' of the text provided. In contrast, the distribution of responses amongst those assigned to the 'High' conceptual complexity texts (in red) lies materially to the left, with a modal response of 2 out of 5, reflecting that respondents perceived to have understood 'A small amount of it (less than half)'. Comparing the tails of these distributions, around 10% of respondents assigned to each of 'Low' and 'Medium' conceptual complexity perceived to have understood 'All or nearly all of it' (5 out of 5), compared to only around 5% of respondents assigned to 'High' conceptual complexity, while around 10% of each of 'Low' and 'Medium' conceptual complexity respondents understood 'None or nearly none of it' (1 out of 5), compared to around 20% of respondents amongst the 'High' conceptual complexity texts.

Across texts that vary in semantic complexity, we see less material differences in distributions, for given levels of conceptual complexity. For instance, increasing semantic complexity from 'Low' (solid lines) to 'Medium' (dashed lines) does not materially change the distribution of responses. Moreover, increasing semantic complexity to 'High' (dot-dashed line) does not materially change the distribution of responses, lying only marginally to the left of the text of 'Medium' semantic complexity. These observations potentially indicate that increasing semantic complexity may be less material than conceptual complexity in impacting people's perceptions of how much information they are able to understand. We see similar patterns in relation to respondents' sentiments towards the central bank in Figure D.1

in Appendix D.[36]

5.2 Causal effects

5.2.1 Conceptual complexity matters most

We empirically test whether observed differences in responses across texts reflect statistically robust causal effects, conditioning on respondents' pre-treatment level of informedness, pre-treatment level of trust in UK institutions, and a range of demographic characteristics. We run the following baseline regression specification:

$$\mathrm{Y}_{q,i} = \beta_1 + \sum_{k=2}^{6} \beta_k \mathrm{Text}_{k,i} + \delta X_i + \epsilon_i \tag{10}$$

where $\mathrm{Y}_{q,i}$ represent responses to questions q capturing respondent i's perceived understanding, actual understanding, and sentiments towards the CB. $\mathrm{Text}_{k,i}$ represents the information treatment that respondent i is randomly assigned to, with β_k representing the associated estimated coefficient for $k \in \{2, 3, 4, 5, 6\}$. β_1 is the intercept, which represents the average response amongst respondents who are randomly assigned to Text 1 with 'Low' semantic and conceptual complexity, which we use as our 'baseline' treatment. X_i represents a set of conditioning variables specific to individual i, including their pre-treatment level of interest, informedness, and trust in the central bank, as well as demographic characteristics. We condition on a restricted set of pre-treatment and demographic characteristics that we find to be most important in explaining variation in the data, including respondents' pre-treatment understanding of monetary policy and macroeconomics, their pre-treatment trust in the central bank, and whether they studied economics at university.[37] ϵ_i is the error term. Each of the β_k coefficients can be interpreted as the estimated causal marginal effect on our dependent variables of interest $\mathrm{Y}_{q,i}$ of being randomly assigned to $\mathrm{Text}_{k,i}$ that is more complex than Text 1, across semantic and / or conceptual dimensions, conditioning on respondent i's demographic characteristics and pre-treatment informedness. We adjust standard errors as per the recommendations in List et al. (2019, 2023) to account for the risk of false positives in experimental settings.[38]

Table 3 reports the results from our baseline regressions. Columns (1)-(3) relate to respondents' perceived understanding (out of 5) of the hypothetical central bank report that they read. The top row reports the estimated constants, reflecting the perceived level of understanding amongst the 'baseline' group who were exposed to Text 1. Rows 2-6 then report the causal marginal effects on respondents' perceived understanding of having instead been randomly assigned to the more complex Texts 2-6, relative to the baseline. Column (1) reports the results from a specification with no controls and no adjustments to standard errors, column (2) reports the results controlling for important de-

[36] We do not plot the distribution of responses for respondents' 'actual' understanding of information, as this is captured on a binary 'correct' or 'incorrect' categorisation, rather than on a 1-5 scale. Regression results for these responses are reported below.

[37] We show in Table D.3 in Appendix D that our empirical findings are very similar when conditioning on a more extensive set of demographic characteristics.

[38] Given that our empirical analysis involves simultaneously testing multiple different treatments $\mathrm{Text}_{k,i}$ across multiple different dependent variables of interest $\mathrm{Y}_{q,i}$, we follow the methodological approach proposed by List et al. (2019) to account for the risk of false positives arising from multiple hypothesis testing. As such, reported standard errors are 'multiplicity adjusted' across each of the seven regression results that we present.

mographic characteristics and pre-treatment priors, while column (3) reports results from our most conservative specification, with multiplicity-adjusted standard errors to account for the risk of false positives. Focusing on the latter, we see that accounting for important demographic characteristics and pre-treatment priors, the average perceived degree of understanding amongst respondents in the baseline group was 1.69 points out of 5. Relative to this baseline, sequentially increasing semantic and conceptual complexity from 'Low' to 'Medium' (Texts 2-4) has no statistically significant effect on respondents' perceived level of understanding. However, increasing conceptual complexity to 'High' (Text 5) does significantly reduce respondents' perceived understanding, by approximately 50% (0.85 points out of 5). Increasing semantic complexity from 'Medium' to 'High' does not further reduce respondents' perceived understanding, demonstrated by identical coefficients across Texts 5 and Texts 6. We confirm that conceptual, not semantic, complexity is driving the effects estimated on Texts 5 and 6 through an alternative specification in Table D.2 in Appendix D.

Columns (4)-(12) relate to respondents' actual understanding of the information they read. Specifically, we test this by asking respondents about the inflation rate and interest rate in the hypothetical economy described in the report, as well as their expectations for what might happen to wages in the future – also indicated in the report. Focusing again on the more conservative specification with multiplicity-adjusted standard errors, we see that accounting for demographic characteristics and pre-treatment priors, on average, 31% of respondents answered correctly on the inflation rate in the economy, (column (6)), 34% answered correctly on the interest rate (column (9)), and 67% answered correctly on the expected direction of travel of wages (column (12)). Relative to each of these baselines, we again see no significant reduction in understanding across respondents assigned to Texts 2-4, while we do see significant effects of having been assigned to a text of 'High' conceptual complexity. Specifically, being assigned to Text 5 reduced the likelihood of correctly answering these questions by 42%, 68%, and 31%, respectively. Again, there is then no significant additional effect of increasing semantic complexity to 'High' in Text 6.

We also test the effects of different degrees of complexity on: a broader range of variables capturing respondents' understanding of the hypothetical economy; their uncertainty around future interest rates in the hypothetical economy; their general understanding of macroeconomic relationships, such as how interest rates might be expected to change in the event of a recession; as well as their posterior beliefs about the UK's inflation target.[39] The results across the range of variables are reported in Table D.5 of Appendix D. Across the board, high conceptual complexity is negatively associated with understanding and positively associated with uncertainty, but estimates on these variables are not statistically significant once we adjust standard errors to account for multiple hypothesis testing.

Columns (13)-(21) relate to respondents' sentiments towards the BoE, after we informed respondents that the hypothetical central bank report they read is similar in style to that published by the BoE. Specifically, we test the degree to which respondents feel as though they now have more trust in the BoE, are likely to pay more attention to future documents published by the BoE, and have a better understanding of the role of the BoE. Across the baseline group, and accounting for demographic

[39]The motivation for testing respondents' general understanding of macroeconomic relationships after having read the report relates to the proposal in Haldane et al. (2019) that a key objective of central bank communications should be to 'educate' the general public on monetary policy and macroeconomics.

characteristics and pre-treatment priors, respondents reported 1.56 points out of 5, on average. Once again, we see that increasing conceptual complexity to 'High' reduces the degree to which respondents' believe they: have more trust in the BoE by 14% (0.22 points out of 5); are more likely to pay attention by 16% (0.36 points out of 5); and have a better understanding of the BoE's role by 26% (0.51 points out of 5). Increasing semantic complexity to 'High' does not then significantly reduce sentiments further.[40] These findings complement recent evidence investigating the determinants of households' trust and credibility in central banks (see Ehrmann et al. (2023), Eickmeier & Petersen (2024*a*,*b*).[41]

Table 3: Causal effects of treatments

Note: The table reports the regression results from the baseline specification described in Equation 37. Columns (1)-(3) report the effects on respondents' perceived understanding, based on responses to Q21.: '*To what extent are you able to understand the content and messages of the material you just read?*', with options ranging from (1) *None or nearly none of it*' to '(5) *All or nearly all of it*'. Columns (4)-(12) report the effects on respondents' actual understanding, based on responses to Q23: *What is the current inflation rate in the hypothetical economy?*, Q26: *What is the current interest rate in the hypothetical economy?*, and Q24: *What do you expect to happen to pay? 'Rise', 'Stay about the same', or 'Fall'.* The correct answers to each are 3%, 0.5%, and 'Rise', respectively. Columns (13)-(21) report the effects on respondents' sentiments towards the BoE, based on responses to Q32: *To what extent do you agree with each of the following statements:* (i) *Having read the document, I now have a better understanding of the role of the Bank of England*; (ii) *Having read the document, I am now more likely to pay attention to future documents published by the Bank of England*; and (iii) *Having read the document, I now have more trust in the Bank of England as an institution*, with options ranging from '(1) *Disagree Strongly*' to '(5) *Agree Strongly*'. Our baseline results are reported in the third column for each dependent variable, controlling for important demographic characteristics and pre-treatment priors, as well adjusting standard errors on the estimated treatment effects to account for multiple hypothesis testing a la List (2020). For comparison purposes, we also provide results for specifications that instead do not adjust standard errors and exclude controls.
*p<0.1; **p<0.05; ***p<0.01

5.2.2 Discussion

There are a number of points worth noting in relation to our results.

Threshold effects of conceptual complexity, captured by the CCI.
Our empirical findings identify not only that conceptual dimensions of complexity matter more than semantic dimensions in impacting people's understanding and sentiments, but also that its effects are

[40] We also capture respondents' sentiments towards the BoE based on other questions asked in the survey, such as whether they wish to 'sign up to more updates' from the BoE or whether they would be willing to 'take part in future CB communications studies'. We report the results based on these additional questions in Table D.6 of Appendix D. High conceptual complexity is also negatively associated with sentiments captured by these questions, but these estimates are not statistically significant once we adjust standard errors to account for multiple hypothesis testing.

[41] Across the range of regressions that we run, we see that the inclusion of controls hardly alters the estimated coefficients while increasing the precision of the estimates. This acts as further evidence supporting the effectiveness of our randomisation of respondents and the even balance of characteristics across treatment arms. The multiplicity-adjustment, meanwhile, increases the standard errors for each of the estimates as expected.

non-linear. That is, we see no effects on people's beliefs of increasing semantic complexity to any degree, or of increasing conceptual complexity from 'Low' to 'Medium'. However, above a certain threshold level of conceptual complexity, between 'Medium' and 'High', people's ability to accurately process information falls significantly, as does the likelihood of them forming positive sentiments towards the central bank. Moreover, we show that this threshold level of complexity relates not just to the quantity of jargon in the reports – the PoJ remains the same between the 'Medium' and 'High' conceptual complexity texts – but in the *range* of topics covered and the *breadth* of jargon used within these topics – as captured by the CCI. The BoE's VS typically lies below this threshold level, while the MPS typically lies on or above the threshold.

Linking the empirical findings to the model.
Our simple theoretical framework describes how complex language may influence the degree to which central bank messages 'get through' effectively to the general public. Specifically, we proposed that complexity reduces informedness amongst households by increasing *costs* of paying attention to central bank communications. Consistent with this hypothesis, Columns (16)-(18) of Table 3 show that (high conceptual) complexity indeed significantly reduces the likelihood of people being willing to pay attention to such central bank communications in the future, with repercussions for engagement and informedness.

Moreover, our empirical findings highlight two further possible channels through which complexity may impact central banks' ability to 'get through' to the public. First, even when people *do* pay attention, (highly conceptually) complex language reduces the accuracy with which people understand the information. Specifically, we find that respondents broadly exerted a similar amount of effort across treatment arms, demonstrated by similar times taken to complete the survey across reports.[42] Despite exerting similar levels of effort, respondents' understanding of information falls at high degrees of conceptual complexity. Our findings can thus be interpreted as identifying a direct effect of complexity on people's information-processing capabilities. This implies that, *for given levels of effort or attention* paid to central bank communications, above a threshold level of conceptual complexity, people are likely to receive a noisier signal and messages will not 'get through' as effectively.

Second, we show that (highly conceptually) complex language also reduces respondents' trust in the central bank. These results, in turn, indicate that complexity may not only impact the *costs* of engaging with central bank communications, but also the (at least, perceived) *benefits* of doing so. If households believe that they will not understand the information, or do not fundamentally trust the institution delivering that information, then the benefits they face to paying attention to that information is reduced.

[42]The average time taken to complete the survey ranges from 17.5 - 18.8 minutes, with standard deviations ranging between 7.1 - 8.4 minutes. These are not statistically significantly different in a t-test. Summary statistics on the time taken across each treatment arm are reported in Table C.2 of Appendix C. One might have expected the time taken to complete each survey to have varied across treatments depending on the degree of complexity. There are a number of possible explanations for why we do not observe this in our survey. First, there may be competing factors influencing the time taken to read more complex reports: on the one hand, some respondents take more time to try to understand the information; while on the other hand, some respondents may give up sooner. These competing effects may have canceled out over the distribution. Second, the experimental setting may provide additional incentives to exert effort trying to understand the information provided, relative to the real-world. We discuss the implications of this and the generalisability of our results in more detail in Section 5.3 and 6.

Other important characteristics.

We report in Table D.3 the full regression table with the estimated coefficients also on our control variables. As expected, pre-treatment level of knowledge about monetary policy and the central bank is a key determinant of the degree to which they understand the information they are treated with. However, another key determinant is respondents' pre-treatment level of trust in the central bank. This complements recent evidence by Hoffman et al. (2023) identifying trust as a key factor in households' inflation expectations formation, as well as theoretical work by Haldane et al. (2019). Moreover, we see that the most consistently important demographic characteristic across the board is whether respondents studied economics at university. Amongst other demographic characteristics, males report higher levels of perceived understanding and have more positive sentiments towards the central bank, while people born in the UK have less positive sentiments than those born outside the UK . Accounting for each these characteristics and pre-treatment levels of understanding and trust; age, income, and education are less important.

5.3 Threats to the internal validity of our results

There are two points worth addressing related to the internal validity of our findings. The first relates to the incentive mechanisms in our experimental design. The second relates to whether the 'ceteris paribus' condition holds across our treatment arms, or whether some unobserved factor could independently be driving our empirical results. We address each in turn.

5.3.1 Incentives in our experimental design

We obtain survey participants through a company called 'Prolific', which pays participants a fixed amount to take part in the survey based on the estimated time taken to complete it, given the number of questions. In our experiment, participants were paid XX given an estimated duration of XX minutes. Although we do not provide participants with performance-based financial incentives, for instance, rewarding correct survey responses, participants have a 'credit score' with Prolific based on the amount of effort they put in to the surveys they fill out. If credit scores fall below a certain threshold people will no longer be eligible to take part in Prolific surveys and receive payments for doing so. Nevertheless, one concern may be that participants just 'click through' the survey without paying attention to any of the questions or information provided. We draw on three pieces of evidence indicating that respondents *did* exert an appropriate amount of effort in completing the survey. First, we explicitly monitor whether respondents are paying adequately close attention to the survey by conducting attention checks at random points during the survey.

Only two respondents out of our sample of 1859 survey participants did not correctly answer the pre-information treatment attention check, while only fourteen respondents did not correctly answer the post-information treatment check, spread broadly evenly across treatment arms.[43] Second, the average time taken to complete the survey across respondents was 17 minutes – close to the *estimated* completion time of XX minutes – the lower quartile was around 12.5 minutes and the minimum time taken was 5 minutes.[44] Third, we see no systematic differences in effort exerted across treatment arms: those respondents who answered the attention check questions incorrectly were broadly evenly split

[43] We confirm that our results are unchanged whether we include or exclude these respondents from our sample.

[44] We calculate this average excluding the top 1% of durations, given a small number of anomalous times taken on the right-hand tail of the distribution.

across treatments; while, as discussed in Section 5.2.2, there were no systematic differences in time taken to complete the survey across treatments. Taken together, these results indicate that people broadly spent an appropriate amount of time and effort filling in the survey, trying to understand the information provided, and answering the questions. Moreover, to the extent that we seek to glean insights from our experiment into the ability of central banks to 'get through' to the public, offering performance-based financial incentives to respondents may hinder the generalisability of results by directly skewing the relative costs and benefits of paying attention to information communicated by the central bank, relative to the real world. We discuss external validity in more detail in Section 6.

A separate concern relating to incentives may be that respondents do not answer *truthfully*. Drobot et al. (2024) show, for instance, in a survey of US households that respondents who voted against the incumbent government at the last election are more likely to report lower levels of trust in US national institutions, lower levels of perceived growth, and higher perceived inflation targets. To the extent that such characteristics may be systematically correlated with the treatment, this could bias the empirical findings. We do not believe this concern applies to our experiment for two reasons. First, in relation to our results identifying varying levels of 'actual' understanding across treatment arms, these findings are based on questions asking for objective information on a *hypothetical* economy and a *hypothetical* central bank. Consequently, they should be less sensitive to 'partisan' sentiments associated with the performance of a specific national economy.[45] Second, we show in C.3 of Appendix C that pre-treatment priors and demographic characteristics are balanced across treatment arms. In particular, amongst these pre-treatment priors, we directly ask respondents how much they 'trust' UK national institutions, such as the central bank, which we explicitly control for in all our baseline regression specifications.

5.3.2 Other possible drivers of our results?

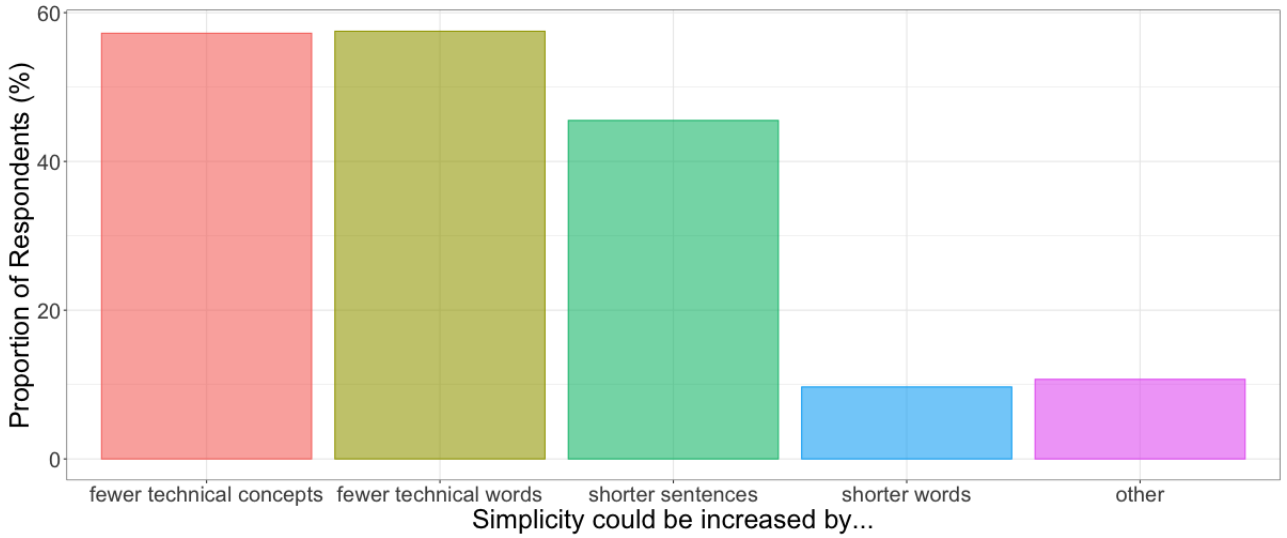

Our experimental design seeks to identify the causal effect of varying the degree of linguistic complexity of information on people's beliefs. In particular, in order to identify the respective effects of semantic and conceptual dimensions of complexity, we hold constant the degree of complexity across one dimension, when changing the degree of complexity across another, across treatment arms. In doing so, we seek to ensure that the 'ceteris paribus' condition holds such that – aside from the change in complexity – all else that may influence people's understanding of information or their sentiments towards the central bank remains equal across treatments. In particular, there are two factors that are important to consider.

First, naturally, the underlying information conveyed in each treatment must be the same. We ensure this is the case, as described in detail in Section 4, by deriving each of our information treatments from quarterly reports published by the same institution (Bank of England) in the same quarter (2018 Q1). We then adjust the text only to replace context- and timing-specific references, and to vary the degree of complexity by replacing or adding jargon terms and tweaking the length of sentences. As such, the underlying information conveyed across treatments should be identical.

[45] Indeed, we show in Table D.3 that prior levels of trust in UK national institutions, such as the central bank, is orthogonal to respondents' 'actual' understanding of the information provided in the treatments.

Second, it might be the case that in varying the degree of linguistic complexity across texts, other – for instance, social or psychological – textual characteristics change too. For instance, a recent literature has emerged noting the importance of communicating in a style that is relatable, personable, and empathetic for engaging with the general public Bholat et al. (2018). Yet, more conceptually complex language is, by definition, more technocratic and less personable. Indeed, using metrics proposed by Pennebaker et al. (2023) to evaluate the social and psychological nature of text, we see that higher conceptual complexity is also associated with higher 'analytic complexity' (reflecting "formal, logical and hierarchical thinking"), lower 'authenticity' (reflecting a measure of "openness and honesty"), less 'clout' (reflecting a more "tentative, humble, and anxious style"), and a less positive 'tone' (reflecting a less "upbeat style"), summarised in Table B.2 in Appendix B.2.3. To the extent that conceptual complexity is *intrinsically* associated with such social and psychological textual characteristics, this does not represent an identification issue with our experiment. If, instead, these factors were explaining our results *independently* of the degree of conceptual complexity, this would represent a problem. To address this potential concern, we seek to glean insights into the fundamental drivers of our empirical results by directly asking respondents what would have made the text easier to understand. The responses are reported in Figure 3.

Figure 3: What would make the text simpler to read?

Note: This figure reports responses to Q33: *Which of the following do you think would have made the text easier to understand? (Please select any that apply)* '*Shorter sentences*', '*Shorter words*', '*Less reference to technical concepts*', '*Fewer technical words*', *Other*'.

We see from Figure 3 that nearly 60% of respondents noted that technical words and technical concepts were the greatest barriers that they faced to understanding and engaging with the information provided.Fewer respondents identified features related to semantic complexity, such as shorter sentences (50%) and shorter words (10%). Meanwhile, 10% reported that there was something 'other' than these features that impacted their understanding, specifying what this 'other' barrier may be with a free text answer. Figure D.2 in Appendix D reports the word cloud of responses, where the size of the word reflects the frequency with which it was raised by respondents. We see that, even amongst the 199 respondents who selected 'other' in Q33, respondents continued to point to conceptual complexity as a barrier, with 'technical' (mentioned by 20 respondents), 'concepts' (also mentioned by 20 respondents),

and 'terms' (mentioned by 11 respondents) amongst the most common responses provided. Meanwhile, only a handful of respondents explicitly referenced features related to the relatability or personability with, for instance, three respondents referencing the 'tone' of the text. We use this as further evidence in support of attributing the empirical results we identify in our experimental design to conceptual complexity.

6 External validity of our findings

We view our experimental study and the empirical findings therein as representing a first test of a novel hypothesis – the quantitative importance of *conceptual* complexity in communicating information effectively – establishing a causal effect. As List (2020) argues, "*in such cases, external validity serves as an 'extra credit' component*". Nevertheless, our study also encompasses features that provide confidence in the generalisability of a range of our empirical findings, for instance in guiding policymakers to achieve their aims of communicating effectively with broader audiences. We discuss the generalisability of our findings within the 'SANS' external validity framework devised by List (2020); evaluating selection, attrition, naturalness, and scaling features of the study.

6.1 Sample Selection

We view the selection of the sample as the feature that merits primary consideration. In particular, we consider the generalisability of two distinct conclusions drawn from our experimental study: (i) the negative effect of conceptual complexity on people's information-processing capacity; and (ii) the implications of this for central banks' ability to 'get through' to broader audiences.

The former, (i), is relatively straightforward. Our experiment is based on a representative sample of the UK general public, and was conducted in July 2021 when inflation was around target levels. As shown in Section 4, characteristics within our sample are consistent with documented demographic features of the broader UK population, while pre-treatment degrees of informedness about the macroeconomy – for instance in knowledge about who sets interest rates, or the distribution of inflation expectations – are consistent with stylised facts across a number of low-inflation developed economies, such as the UK, US and Eurozone. This provides us with confidence that the causal effects identified are generalisable to broader populations of people living such low-inflation economies, during periods of low inflation. This is consistent with arguments made in related information-provision experiments based on similar survey designs, such as by Coibion et al. (2022), Bholat et al. (2018), and D'Acunto, Hoang & Weber (2020). We are cautious, however, about generalising our results to high-inflation periods or to economies where inflation has historically been high, which studies show influences people's attentiveness to new economic information (Weber et al. 2023). Future research could extend our analysis to such settings.

On (ii), drawing general implications from our findings for central banks' ability to 'get through' to the general public, the representativeness of our sample sparks a rather different discussion. In particular, one potential concern about our experimental setting may be that, in practice, people do not typically read central bank reports directly. Rather, they are likely to receive a transmitted signal of the report via, for instance, the media. This represents an external validity challenge only insofar as the signal

that the public receives from the media is always perfectly simplified and perfectly precise, regardless of the original degree of complexity in the central banks' report. To the extent, instead, that technically trained individuals are also impacted by complex information, or that journalists are also rationally inattentive, the public may nevertheless receive a complex and / or noisy signal of the central banks' message. As such, our empirical findings would yield generalisable implications for central banks' ability to 'get through'. We provide in Appendix A.2 an extension of the simple theoretical model constructed in Section 2 to describe the transmission of the central bank's message to the public via a rationally inattentive intermediary agent (such as a journalist). We provide in this section two pieces of evidence that support the external validity of our findings.

6.1.1 High conceptual complexity also impacts technically trained individuals.

First, from our experiment, we are able to explicitly test the degree to which complex language affects not only a representative sample of the UK population, but also *technically trained* individuals, by restricting our sample to a sub-set of participants who studied economics at university. To do so, given the smaller sample size of this specification, we run a simplified version of the baseline regression described by equation (37) in which we consider all respondents assigned to 'High' conceptual complexity texts (Texts 5 and 6) as 'treated', relative to the 'control' group of respondents not assigned to these texts (Texts 1, 2, 3, 4). Table 4 reports the results of our analysis on this sub-sample.[46]

Table 4: Effects of 'High' conceptual complexity on respondents who studied Economics at University

	Dependent variable:						
	Understanding	Inf(t)	Int.Rate(t)	Exp Pay	Trust	Attention	BoE Role
	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Constant (Texts 1-4)	1.49***	0.11	0.24*	0.59***	1.98***	2.90***	2.68***
	(0.24)	(0.13)	(0.13)	(0.13)	(0.21)	(0.26)	(0.25)
Marginal effect of:

	(0.22)	(0.07)	(0.07)	(0.09)	(0.12)	(0.19)	(0.16)
Sample	Econ	Econ	Econ	Econ	Econ	Econ	Econ
Controls	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Multip. adj. SEs	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Observations	298	298	298	298	298	298	298
Adjusted R^2	0.30	0.05	0.09	0.05	0.12	0.06	0.04

Note: *p<0.1; **p<0.05; ***p<0.01. The table reports the regression results from a modified version of the baseline specification described in Equation 37 in which we compare 'treated' respondents assigned to Texts 5 and 6 with 'High' conceptual complexity (CC) with a 'control' group of respondents assigned to Texts 1-4 with 'Low' or 'Medium' conceptual complexity. The dependent variables are defined as in Table 3, and the control variables are the same. All standard errors are adjusted to account for multiple hypothesis testing a la List (2020).

[46] We report the results from balance tests in Table C.4 of Appendix C, confirming that demographic and pre-treatment characteristics across the sub-sample of respondents who studied economics at university are not statistically significantly different across treatments.

We see that, nearly across the board, the negative marginal effect of having been assigned to a 'High' conceptual complexity report remains significant even across this sub-sample of respondents who are not only highly educated but also specifically trained in economics. That is, 'High' conceptual complexity causally and materially reduces people's *perceived* understanding of the information conveyed, their *actual* understanding of this information, and their sentiments towards the central bank, amongst respondents who studied Economics at university. To the extent, then, that high conceptual complexity impacts also technically trained individuals' understanding of information communicated by the central bank, this has broader implications for central banks' ability to communicate with a *range* of audiences, and for the likelihood that technically skilled individuals – such as journalists – would necessarily always be able to perfectly precisely transmit and simplify these messages to the public, even if they wanted to.

6.1.2 Journalists can transmit a noisy and complex signal of the BoE's original message.

Second, we leverage text data on newspaper articles reporting on BoE interest rate decisions in August 2016, August 2017, and November 2017 to directly compare their degree of complexity and precision with that of the original BoE publication. The BoE changed interest rates in August 2016 (25bps cut) and November 2017 (25bps hike), and kept them unchanged in August 2017. November 2017 was the first period in which the VS was introduced. The newspapers include broadsheet press articles from: the Financial Times (FT), Guardian, Telegraph, and City A.M.; news agency press articles from Sky News and the Press Association; and tabloid press articles from the Daily Express, Daily Mail, Daily Mirror, Daily Record, Daily Star, Metro, Mirror, Spectator, and London Evening Standard. We focus on articles published on or during the 7 days after the BoE's interest rate decision (and accompanying quarterly report) that contain reference to 'Bank of England' or 'Inflation Report' (now termed 'Monetary Policy Report'). This leaves us with 102 articles in total across the three quarters.

We measure the complexity of media articles using the CCI constructed in Section 3. We calculate the CCI on the proportion of each media article devoted to monetary policy-relevant discussion by exploiting Natural Language Processing methods – namely, an unsupervised Latent Dirichlet Allocation (LDA) topic model a la Blei et al. (2012) trained on the BoE and media reports – and measure the CCI based on the length of the BoE-relevant text.[47] Not accounting for this would bias the CCI downwards.

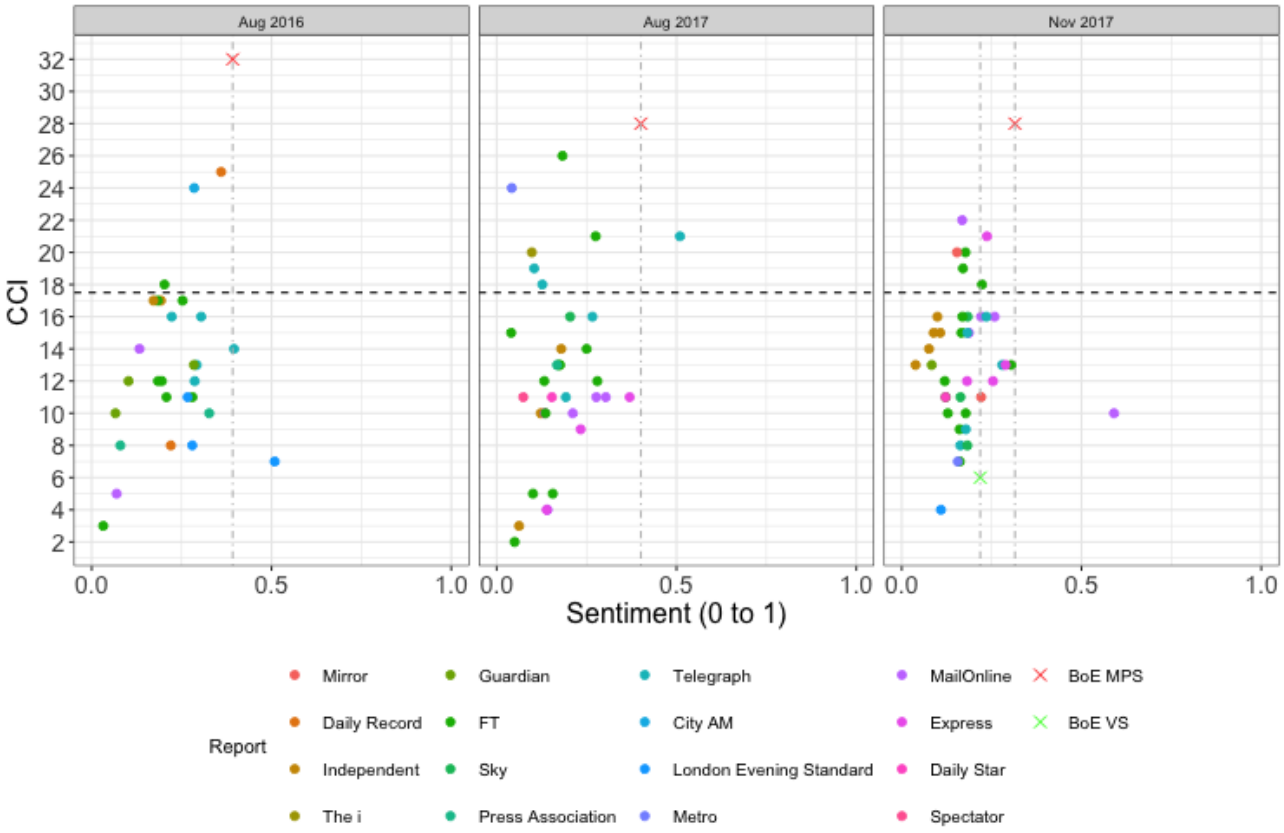

We capture the degree to which media articles transmit a 'similar' message to that conveyed by the original BoE report based on the 'sentiment' of the respective reports. A growing literature has identified the importance of the 'sentiment' of central bank reports in driving inflation expectations and financial market responses Hubert & Labondance (2017). If, however, the true sentiment of the central bank is not being conveyed by media articles transmitting that message, then this hinders the central banks' ability to effectively anchor expectations. We leverage a fine-tuned Large Language Model

[47]Specifically, we train an LDA topic-model on a corpus of text comprising the BoE's MPS and MPR and all of the media articles *in each period*. We do this for each individual period at a time so as to accurately identify the monetary policy-relevant topics in that period, which may change over time. We then run the model using Gibbs sampling with 1000 iterations to categorise text into five topics across the corpus and to identify their coverage across reports. We then apply judgment to identify the monetary policy-relevant topics. In each period, the LDA model appears to perform well in distinguishing between these and less relevant topics, which in contrast make up a negligible part of the BoE reports. For instance, in 2016 Q3 the model identifies a non-monetary policy-related topic in which important words include "Chancellor", "Hammond", "tax", "fiscal", and "Brexit". We provide a list of the topics identified and top words in each topic in Figure E.3 of Appendix E.

(LLM) constructed by Pfeiffer & Marohl (2023) called 'CentralBankRoBERTa' designed specifically to capture the emotional sentiment of central bank communications, on a 0-1 scale (reflecting negative-positive sentiments).[48] The closer the sentiment of the media articles reporting on the BoE decision, the more similar is the underyling message they are conveying to that originally communicated by the BoE.

We plot in Figure 4 a scatterplot depicting the conceptual complexity (y-axis) and sentiment (x-axis) of BoE reports and the media articles transmitting their message.

Figure 4: Complexity and precision of media articles reporting on BoE decisions

Note: Figure 4 reports the conceptual complexity (y-axis) and 'sentiments' (x-axis) of BoE reports and media articles reporting on the BoE decision in 2016 Q3 (left-hand panel), 2017 Q3 (middle panel), and 2017 Q4 (right-hand panel). Conceptual complexity is measured by the CCI, as constructed in Section 3. Sentiment is calculated by the Pfeiffer & Marohl (2023) CentralBankRoBERTa LLM model, capturing the emotional sentiment of central bank communications on a 0-1 scale where 0 reflects negative emotion, while 1 reflects positive emotion. BoE reports are represented by crosses (red for the MPS, green for the VS), media articles are represented by dots (with colours reflecting the media outlet). The horizontal dotted line reflects the 'Medium' degree of conceptual complexity from the information treatments in the experiment conducted in Section 4. The vertical dotted line reflects the 'sentiment' of the BoE's MPS and VS in each quarter.

Focusing first on the complexity of the reports (y-axis), we compare that of BoE publications (crosses) with that of the media articles that are reporting on the BoE's decision (dots). As depicted in Figure 1bii, the MPS has a CCI of around 30 in each of these quarters. The complexity of the media articles,

[48] We follow the recommendations of Hayo & Zahner (2023) in using machine-learning models, rather than dictionary-based methods, to measure sentiment due to their superior ability to account for the contextual meaning of words.

in contrast, varies greatly both across and within media outlets in different periods. While a large proportion of media articles do report messages that are simpler than those of the original BoE MPS reports, a significant number of articles remain rather conceptually complex. In particular, a number of articles in each period have a CCI that lies above 17.5 (horizontal dotted line) – corresponding to the 'Medium' level of conceptual complexity in the experiment conducted in Section 4 – above which we identified a threshold level of complexity that significantly reduces people's ability to understand information. The more complex articles include publications by City A.M., Daily Record, Express, Financial Times, MailOnline, Spectator, Telegraph, and the I. Noticeably, this remains the case in November 2017, despite the introduction of the simpler BoE VS alongside the (still) complex MPS. Indeed, we show in E.4 in Appendix E that, in each period, the majority of jargon terms used in media articles are a sub-set of those used in the BoE MPS reports published that period, and are nearly an exclusive sub-set of those used in the BoE MPR reports. As such, these observations indicate that: media articles do not *necessarily* simplify the BoE's message to a degree that makes it accessible to the general public; and that conceptual complexity in the BoE's original report (particularly the MPS) directly filters through to conceptual complexity in media articles transmitting that signal (and despite the introduction of an additional simpler report). Both observations imply that central banks could 'get through' more effectively to the general public by reducing the conceptual complexity of each of their publications even in a world in which the general public receive the message they communicate exclusively via the media.

On the content of the messages (x-axis), the vertical dotted line represents the sentiment of the message conveyed by the BoE's MPS in each period, as well as that conveyed the BoE's VS in November 2017. We see a wide range of sentiments conveyed in articles both across and within media outlets.[49] Very few articles reporting on the August 2016 and August 2017 BoE interest rate decisions precisely report a message with the same sentiment as that conveyed by the BoE's MPS in that period (vertical dotted line), with most articles reporting a message that is – in a number of cases, considerably – more negative (lying to the left of the dotted line). Similarly, articles reporting on the November 2017 decision also convey a sentiment that is more negative than that in the MPS. Noticeably, however, the sentiment of the articles in this period is, observationally, less dispersed and more tightly concentrated around the sentiment in the BoE's (less complex) VS. We are agnostic, based on this analysis in isolation, as to the *cause* of the discrepancy in sentiment between the BoE publications and the media articles reporting on them, or the variation in dispersion across periods. Factors contributing to the discrepancy in sentiment could include intentional (partisan) biases on the part of the media outlet or, in light of the experimental results presented above in Table 4, unintentional biases arising, for instance, from the high degree of conceptual complexity in the original BoE report. Similarly, it is possible that the introduction of the simpler VS helped to tighten the dispersion of the message conveyed by the media. Future research should investigate this relationship further. Either way, for the purposes of this paper, the fact that the BoE's underlying message seems to be transmitted noisily to the general public via the media, implies that central banks could better anchor expectations by communicating more directly with the general public – as advised by Haldane et al. (2019). However, in order to do so and 'get through' effectively, they should simplify their communications.

[49] We are unable to measure the sentiment of the BoE's MPR using the CentralBankRoBERTa model, given the very large length of the report.

6.2 Attrition, Naturalness, and Scaling

We turn now to the other key features of the List (2020) SANS framework. On attrition and compliance rates, the survey company we use provides data points only on survey participants who completed the survey. Thus, the compliance rates amongst respondents in our empirical results are 100%. On the naturalness of the experiment, the information provided in the information treatment is similar in nature to the broad information communicated by central banks in their quarterly reports. Indeed, the reports we use are adapted from actual Bank of England Visual Summaries and Monetary Policy Summaries. Moreover, we follow the literature in capturing respondents' information processing capacity across key variables of interest, such as inflation, interest rates, and expectations. Finally, future research should complement our initial experimental evidence by scaling up the findings. In particular, future work could explore the effect on different economic actors (such as journalists and financial markets), different settings (such as high inflation economies or periods), as well as other fields and languages by adapting the jargon dictionary to capture relevant technical terminology.

7 Conclusions

Understanding the impediments to information transmission is crucial for policy institutions, who often have to communicate inherently complex messages to a range of different audiences. An established literature on information theory identifies as the principal cost of comprehension the degree of *new* information provided by *specific* words. While a nascent empirical literature has sought to capture the difficulty of comprehending information through quantitative measures of linguistic complexity, measures used to date are restrictive and focus on narrow dimensions of specifically 'semantic' complexity (e.g. average word and sentence length) that do not capture the fundamental information processing costs identified by information theory. We show in this paper that dimensions of 'conceptual' complexity, which seek to operationalise the 'true' costs identified in the literature by capturing the complexity of the *content* of text itself, indeed matter more. Policy institutions could more effectively achieve their aims of 'getting through' to their broad audiences by designing communications based on conceptual, rather than semantic complexity.

We draw these conclusions by making two primary contributions. First, we distinguish between 'semantic' and 'conceptual' dimensions of complexity and construct a novel quantitative measure of conceptual complexity, which complements existing measures of semantic complexity. This measure, which we term the Conceptual Complexity Index (CCI), entirely explains the impact of conceptual complexity on information processing obtained in the experimental study. Though our design and choice of jargon words is specific to the central banking environment we study, the idea could be adapted to any communication environment. We hope that it can broaden future empirical analyses of the two different types of linguistic complexity, and in particular, proves useful in other fields too. As an example of its potential value, we apply the CCI, along with traditional measures of semantic complexity to quarterly Bank of England (BoE) publications. We show that efforts to simplify language have been successful if one focuses only on semantic dimensions of complexity (e.g. the Flesch-Kincaid score). However, the conceptual complexity of its reports, as captured by the CCI, has not followed

the same trend-decline. Instead, conceptual complexity, which we experimentally find to matter more, has *increased* over the same period for certain publications and demonstrated far greater volatility.

Our second contribution is to test the relative importance of semantic and conceptual complexity in an information provision experiment with 1,859 members of the public. We randomly assign respondents to hypothetical central bank reports that vary in complexity across semantic and conceptual dimensions, and show that *conceptual* complexity matters more than semantic. It reduces: (i) respondents' perceived understanding of the report they read, (ii) their actual understanding of the information conveyed, consistent with the predictions of a simple rational inattention model we develop, and (iii) their sentiments towards the central bank (such as trust). In contrast, semantic complexity has little to no effect. Moreover, we show evidence supporting the generalisability of these experimental results: each of these results hold focusing on a sub-sample of highly educated and technically trained respondents who studied economics at university; while conceptual complexity of BoE publications filters through to media articles reporting on them, which can remain highly complex and commonly report an imprecise signal of the original message. Taken together, our findings have potentially important implications for effective communications with a range of actors in the economy, not just the general public.

Our work has important and clear implications for policy institutions such as central banks. If they wish to 'get through' to their broad audiences, they should pay close consideration to the complexity of the language they use. In particular, they should focus on broader dimensions of complexity than those captured by the restrictive measures used by both the research literature and policy institutions to date. Our results suggest that conceptual complexity is particularly important, not just in relation to inflation expectations, but people's understanding of information more generally, as well as their sentiments towards the central bank. Our results also suggest that conceptual complexity matters not only for effective communications with the general public, but potentially also for *all* economic agents.

Appendix A Theoretical Model: Derivations and Extensions

A.1 Derivations for the Simple Model

A.1.1 Relating λ_h to ξ_h

Information Processed, λ_h
The entropy $H()$ of a normally distributed random variable with variance σ^2 is: $\frac{1}{2}log(2\pi e\sigma^2)$. Thus, the quantity of information chosen by household h can be expressed as:

$$\begin{aligned}\lambda_h &= H(x) - E[H(x|s_h)] \\ &= \frac{1}{2}log(2\pi e\sigma_x^2) - \frac{1}{2}log(2\pi e\sigma_{x|s_h}^2) \\ &= \frac{1}{2}log\left(\frac{\sigma_x^2}{\sigma_{x|s_h}^2}\right)\end{aligned} \tag{11}$$

where $\sigma_{x|s_h}^2$ is the posterior uncertainty that household h has about the true message, x, given the signal, s_h.[50] The reduction in uncertainty about x given the signal, s_h, is characterised by the ratio $\frac{\sigma_x^2}{\sigma_{x|s}^2}$. The smaller is $\sigma_{x|s}^2$ relative to σ_x^2, the greater is the reduction in uncertainty given the acquisition of the signal and, thus, the greater is the quantity of information processed. The entropy function $H()$ can be thought of as describing 'disorder' associated with x. Hence, the more we seek to reduce the uncertainty about x given the signal, s_h, (that is, the smaller is $\sigma_{x|s}^2$), the more we *reduce* the expected 'disorder' around x given s_h (that is, the smaller is $E[H(x|s_h)]$), the greater the quantity of information processed, λ_h, by household h.

Weight attached to the signal received, ξ_h
Just as the quantity of information processed, λ_h, by household h is a characteristic of the degree to which it pays attention to the signal received from the CB, similarly, the weight, ξ_h, that household h attaches to the signal, s_h, is also a feature of the degree to which it pays attention to the signal received from the CB. Hence, household h's optimal choice of attention determines *both* its optimal choice of how much information to process, λ_h, *and* its optimal choice of weight, ξ_h, to attach to the signal, s_h.

Given this, it is convenient to likewise define the weight, ξ_h, in terms of the reduction in uncertainty about the true state of the economy as a result of acquiring the signal, s_h:

$$\xi_h \equiv \left(1 - \frac{\sigma_{x|s}^2}{\sigma_x^2})\right) \tag{12}$$

where $\xi_h \in [0, 1]$. The posterior distribution $x|s$ is derived as follows.

We have a prior distribution: $x \sim \mathcal{N}(0, \sigma_x^2)$. The signal, $s = x + \epsilon$ where $\epsilon \sim \mathcal{N}(0, \sigma_\epsilon^2)$ contains noisy information about x. Using s, we can form a posterior distribution of $x|s$ given by:

$$x|s \sim \mathcal{N}(E[x|s], \sigma_{x|s}^2)$$

We can derive $E[x|s]$ and $\sigma_{x|s}$ using Bayes' Rule. Firstly, given that each of x and ϵ are normally distributed, we know that a linear addition of the two is also normally distributed such that:

$$s \sim \mathcal{N}(0, \sigma_s^2)$$

[50] Henceforth, $\sigma_{x|s_h}^2 \equiv \sigma_{x|s}^2$ for simplicity of notation.

In addition, we know that:

$$s|x \sim \mathcal{N}(E[s|x], \sigma^2_{s|x}) \tag{13}$$

where

$$\begin{aligned} E[s|x] &= E[x + \epsilon|x] \\ &= x + E[\epsilon|x] \\ &= x + E[\epsilon] \\ &= x \end{aligned}$$

given that $E[\epsilon|x] = E[\epsilon] = 0$ follows from the independence of ϵ from x. The variance is given by:

$$\begin{aligned} \sigma^2_{s|x} &= Var[s|x] \\ &= E[s^2|x] - E[s|x]^2 \\ &= E[(x+\epsilon)^2|x] - E[(x+\epsilon)|x]^2 \\ &= E[x^2 + 2x\epsilon + \epsilon^2|x] - x^2 - 2xE[\epsilon|x] - E[\epsilon|x]^2 \\ &= E[\epsilon^2|x] - E[\epsilon|x]^2 \\ &= Var(\epsilon) \\ &= \sigma^2_\epsilon \end{aligned}$$

again this holds by independence of ϵ from x. The distribution of $s|x$ can be re-written as:

$$s|x \sim \mathcal{N}(x, \sigma^2_\epsilon) \tag{14}$$

With this, we can write the normal distributions of x and $s|x$ as:

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2_x}} \exp\left\{-\frac{(x - E[x])^2}{2\sigma^2_x}\right\} = \frac{1}{\sqrt{2\pi\sigma^2_x}} \exp\left\{-\frac{x^2}{2\sigma^2_x}\right\} \tag{15}$$

$$f(s|x) = \frac{1}{\sqrt{2\pi\sigma^2_{s|x}}} \exp\left\{-\frac{(s - x)^2}{2\sigma^2_{s|x}}\right\} = \frac{1}{\sqrt{2\pi\sigma^2_\epsilon}} \exp\left\{-\frac{(s - x)^2}{2\sigma^2_\epsilon}\right\} \tag{16}$$

By Bayes' Rule:

$$
\begin{aligned}
f(x|s) &= \frac{f(x)f(s|x)}{f(s)} \\
&\propto f(x)f(s|x) \\
&= \frac{1}{\sqrt{2\pi\sigma_x^2}}\frac{1}{\sqrt{2\pi\sigma_\epsilon^2}}\exp\left\{-\frac{x^2}{2\sigma_x^2}-\frac{(s-x)^2}{2\sigma_\epsilon^2}\right\} \\
&= constant * \exp\left\{\frac{-x^2\sigma_\epsilon^2 - s^2\sigma_x^2 + 2sx\sigma_x^2 - x^2\sigma_x^2}{2\sigma_x^2\sigma_\epsilon^2}\right\} \\
&\propto \exp\left\{\frac{-x^2(\sigma_x^2+\sigma_\epsilon^2) + 2sx\sigma_x^2 - s^2\sigma_x^2}{2\sigma_x^2\sigma_\epsilon^2}\right\} \\
&= \exp\left\{\frac{-x^2 + 2x\frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2} - \frac{s^2\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2}}{2\frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}}\right\} \\
&\propto \exp\left\{\frac{-x^2 + 2x\frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2} - \frac{s^2\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2}}{2\frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}}\right\}\exp\left\{\frac{-(\frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2})^2}{2\frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}}\right\} \\
&= \exp\left\{\frac{-x^2 + 2x\frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2} - (\frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2})^2}{2\frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}}\right\}\exp\left\{\frac{-\frac{s^2\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2}}{2\frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}}\right\} \\
&\propto \exp\left\{\frac{-(x-\frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2})^2}{2\frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}}\right\} \\
&= \exp\left\{-\frac{(x-E[x|s])^2}{2\sigma_{x|s}^2}\right\}
\end{aligned}
$$

where

$$E[x|s] = \frac{s\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2} \tag{17}$$

$$\sigma_{x|s}^2 = \frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2} \tag{18}$$

A density must integrate to unity such that:

$$f[x|s] = \frac{1}{\sqrt{2\pi\sigma_{x|s}^2}}\exp\left\{-\frac{(x-E[x|s])^2}{2\sigma_{x|s}^2}\right\} \tag{19}$$

and the posterior distribution is given by:

$$x|s \sim \mathcal{N}(E[x|s], \sigma_{x|s}^2) \tag{20}$$

where we can sub in from equations (17) and (18) above.

Ultimately, we obtain that: $\sigma_{x|s}^2 = \frac{\sigma_x^2\sigma_\epsilon^2}{\sigma_x^2+\sigma_\epsilon^2}$ and $\xi_h = \frac{\sigma_x^2}{\sigma_x^2+\sigma_\epsilon^2}$. In the case of perfect information where household h faces no constraints on attention, then $\sigma_\epsilon = 0$ and, thus, $\xi_h = 1$.

Combining together

Rearranging and substituting equation (12) into equation (11), we can re-write the quantity of infor-

mation chosen by household h in terms of the weight, ξ_h, they attach to the signal:

$$\lambda_h = \frac{1}{2} log\left(\frac{1}{1-\xi_h}\right) \tag{21}$$

A.1.2 Household Maximisation Problem

Households seek to maximise their expected utility subject to their constraint on attention. Their problem is described by:

$$\max\{E[u_h(x,\tilde{x}_h)] - c_h\} \tag{22}$$

Household h's expected utility function is defined as:

$$E[u_h(x,\tilde{x}_h)] = E_x[E_s[u_h(x,\tilde{x}_h)]] \tag{23}$$
$$= E_x[E_s[-b(x-\tilde{x}_h)^2]] \tag{24}$$
$$= E_x[E_s[-b(x-E[x|s_h])^2]] \tag{25}$$

where equations (24) and (25) follow by substitution from (1) and (4). Notice that $E[x-E[x|s_h]]^2 \equiv \sigma^2_{x|s}$ by definition. Hence, we are able to define the expected utility function in terms of the posterior uncertainty about x, given the acquisition of the signal, s_h:

$$E[u_h(x,\tilde{x}_h)] = -b\sigma^2_{x|s}$$

Finally from (12), we can write the expected utility function in terms of the weight, ξ_h, that household h attaches to the signal:

$$E[u_h(x,\tilde{x}_h)] = -b(1-\xi_h)\sigma^2_x \tag{26}$$

Now both the expected utility function and the cost function are defined in terms of the weight, ξ_h. Hence, we can specify the household maximisation problem wholly in terms of the exogenous parameters and the choice variable, ξ_h, representing the weight that a representative rationally inattentive household h attaches to the signal received from the CB about the state of the economy. Substituting in from equations (2), (11) and (26), we can rewrite the household's problem described in equation (22) as:

$$\max_{\xi_h\in[0,1]}\left\{-b(1-\xi_h)\sigma^2_x - \frac{(1+\mu)}{2} log(\frac{1}{1-\xi_h})\right\} \tag{27}$$

The first order condition is:

$$\frac{\partial max}{\partial \xi_h} = b\sigma^2_x - \frac{(1+\mu)}{2}\frac{1}{1-\xi_h}$$

which yields optimal weight:

$$\xi^*_h = max\left(0, 1-\frac{(1+\mu)}{2b\sigma^2_x}\right) \tag{28}$$

We can see that the optimal signal weight, reflecting the optimal level of attention, increases with the benefit of paying attention, b, and the degree of uncertainty surrounding the state of the economy, σ^2_x. In contrast, attention decreases with the linguistic complexity of the CB's message, μ.

A.1.3 Bayesian updating of beliefs

Having determined the optimal weight to attach to the signal, we substitute equation (8) into (4) to obtain the corresponding posterior belief is given by:

$$\begin{aligned}\tilde{x}_h &= E[x|s_h] \\ &= \xi_h^*(x+\epsilon_h) \\ &= \left(1-\frac{(1+\mu)}{2b\sigma_x^2}\right)x+\eta_h\end{aligned}$$

where $\eta_h \equiv \xi_h^*\epsilon_h \sim \mathcal{N}(0,\sigma_\eta^2)$ can be interpreted as resulting noise in actions.[51] Ultimately, the deviation of the posterior belief from the true message communicated by the CB is given by:[52]

$$x-\tilde{x}_h = \frac{(1+\mu)x}{2b\sigma_x^2}-\eta_h \tag{29}$$

A.2 Extension: Role of Journalists

In the real world, most people get their information about the state of the economy via the media, rather than directly from the CB (Lamla & Lein 2010, Lamla & Maag 2012, van der Cruijsen et al. 2010, 2015). In this section, we draw on the empirical finding presented in Section **??** (coined 'Result 4') that complexity also impacts highly educated individuals with university degrees in economics, to describe how complexity may still play a pervasive role in reducing the accuracy of expectations formed by economic actors, in a setting in which the media first receives, simplifies, and transmits the CB's message. Specifically, we extend the simple model presented in Section 2 to incorporate a role for the media.

A.2.1 Setup and Assumptions

We assume that journalists, j, are also rationally inattentive and receive the CB signal before transmitting it on to final agents, f. The action choice of the rationally inattentive journalist is assumed to be to pay that level of attention to the CB signal which maximises a constrained expected utility function, where utility depends on the difference between the true state of the economy and its posterior belief. The implicit assumption is that a longer-run objective of maximising public engagement (for example, subscriptions) translates via reputation effects associated with the onward reporting of the CB message with a reasonable degree of accuracy. Another assumption imposed is that the media best achieves this objective of maximising public engagement by minimising the cost that final agents face to paying attention to the message that they transmit. This is modelled as an assumption that the message transmitted to final agents by the media is no longer linguistically complex: $\mu = 0$.

Media journalists receive a *noisy* signal from the CB about the true state of the economy. The media optimally choose how much attention to pay to this signal and form a posterior belief about the state of the economy. Before transmitting a signal of their posterior beliefs to final agents, media journalists simplify the language of the original message; so as to achieve their objective of maximising engagement. They then transmit this simplified signal to final agents, who optimally choose how much attention to pay to this. The setup can be summarised by the following propositions.

Proposition 1: Media journalists face exactly the same problem as do final agents in *Scenario 1.* That is, they receive a *noisy* signal about the state of the economy from a message communicated by

[51] The variance of the noise in actions, $\sigma_\eta^2 = (\xi_h^*)^2\sigma_\epsilon^2$ will be small as high attentiveness implies relatively high ξ_h^*, but relatively low σ_ϵ^2 and vice versa. At each extreme, $\sigma_\eta^2 = 0$ as $\sigma_\epsilon^2 = 0$ in the full attention case, whilst $\xi_h^* = 0$ in the no attention case.

[52] Note that this deviation is zero in expectation: $E[x-\tilde{x}_h] = E[x]-E[E[x|s_h]] = E[x]-E[x] = 0$ by Law of Iterated Expectations.

the CB, and optimally allocate attention to this subject to utility and cost functions, $u_m(x, \tilde{x}_m)$ and c_m, that are analogous to those described by equations (1) and (2) respectively.

Proposition 2: Media journalists transmit a signal of their posterior beliefs about the state of the economy to final agents given by:

$$s_f = \tilde{x}_m + \epsilon_f \tag{30}$$

such that, unlike in *Scenario 1*, final agents no longer receive a signal of the true message, x. Instead, they receive a signal of media journalist m's posterior belief, $\tilde{x}_m$. Given that $\tilde{x}_m$ is itself a function of x which is normally distributed, it also holds that $\tilde{x}_m \sim \mathcal{N}(0, \sigma^2_{\tilde{x}_m})$.

Proposition 3: Final agents' utility is exactly the same as that described in Section 2 for the Direct Signal case:

$$u_f(x, \tilde{x}_f) = -b_f(x - \tilde{x}_f)^2 \tag{31}$$

However, now, final agents do not receive a direct signal of the true state of the economy, x. Instead, the best that final agents can do is to use $\tilde{x}_m$ as a proxy for x. Hence, their utility function can be written as:

$$u_f(\tilde{x}_m, \tilde{x}_f) = -b_f(\tilde{x}_m - \tilde{x}_f)^2 \tag{32}$$

such that a final agent, f, seeks to maximise expected utility by minimising the deviation of its own posterior belief, $\tilde{x}_f$, from that of the media journalist, $\tilde{x}_m$. Note that $u_f(\tilde{x}_m, \tilde{x}_f)$ is a good approximation of $u_f(x, \tilde{x}_f)$ if and only if $x \approx \tilde{x}_m$. Nevertheless, the information that final agents acquire about $\tilde{x}_m$ via the signal, s_f, is the only information that they receive that contains any information about x. Hence, seeking to minimise the distance between their posterior belief, $\tilde{x}_f$, and that of the media journalist, $\tilde{x}_m$, is the best that final agents can do in seeking to minimise the distance from the true state of the economy, x.

Proposition 4: The cost to a final agent, f, of paying attention to the linguistically simplified ($\mu = 0$) signal it receives from the media is given by:

$$c_f = \lambda_f \tag{33}$$

where the cost is no longer a function of final agent f's ability, a_f.

Proposition 5: Final agents optimally allocate attention to s_f to maximise the expectation of utility, described by equation (32) subject to the costs, described by equation (33).

A.2.2 Results

By Proposition 1, the weight attached by the media to the signal it receives from the CB is analogous to that described by equation (8), such that the deviation of their posterior belief from the true state of the economy is:

$$x - \tilde{x}_m = \frac{x}{2b_m\sigma_x^2}[1 + (1 - a_m)\mu\sigma_x^2] - \eta_m \tag{34}$$

Final agents solve their maximisation problem of paying optimal attention to the signal received from the media, yielding a deviation of final agent f's posterior belief from media journalist m's posterior belief given by:

$$\tilde{x}_m - \tilde{x}_f = \frac{\tilde{x}_m}{2b_f\sigma_{\tilde{x}_m^2}} + \eta_m - \eta_f \tag{35}$$

Ultimately, the deviation of final agent f's posterior belief from the true message, x, communicated by the CB is arrived at by summing equations (34) and (35):

$$x - \tilde{x}_f = \frac{x}{2b_m\sigma_x^2}\psi + \frac{x}{2b_f\sigma^2_{\tilde{x}_m}}\left(1 - \frac{}{2b_m\sigma_x^2}\psi\right) - \eta_f \tag{36}$$

where $\psi = [1 + (1 - a_m)\mu\sigma_x^2]$.

A.2.3 Discussion

Each of the implications drawn from the simple model presented in Section 2 hold here. Crucially, the model describes how linguistic complexity continues to play a pervasive role in reducing the degree to which final agents form posterior beliefs that lie close to the true state of the economy as communicated by the CB's message, even in a setting in which the media acts as an intermediary.

For simplicity, we have assumed in this model that there is no *additional* noise generated in the process of simplifying the message received from the CB for purposes of disseminating this to the public. In reality, the more complex the original message communicated, the greater the likelihood of some 'lost in translation' noise arising, and the even more pervasive the role of complexity.

Appendix B Jargon Dictionary and Text Analysis

B.1 Jargon Dictionary

We construct a jargon dictionary based on A-Z lists of economics, business, and financial terms published by the Economist, the Guardian, and Investopedia. Our dictionary contains 350 jargon terms in total. We then manually categorise these into 10 topics. The list of terms in our dictionary, by category, is presented Table B.1.

	Monetary.Policy	Inflation	Output,.Production..and.Supply.side	Private.Demand..C.I.	Fiscal.Policy,.incl.G.	Open.Economy	Labour	Financial.Markets	Financial.Stability.Macroprudential.Policy	Other
1	Base rate	CPI	Activity	Capital Expenditure	Budget Deficit	Balance of payments	Discouraged workers	30 Year Treasury	Balance Sheet	Adverse Selection
2	Basis point	Demand pull inflation	Aggregate demand	Consumption	Debt Management Office	Capital account	Economically inactive	Bond	Banking System	Animal spirits
3	Discount Rate	Disinflation	Boom	Corporates	DMO	Commodity cycle	Frictional unemployment	Capital markets	Capital Buffers	Annual equivalent rate
4	Effective Lower Bound	Hyperinflation	Business Cycle	Infrastructure	Fiscal drag	Comparative Advantage	Full employment	Carry trade	Credit	Annual Percentage Rate
5	ELB	IMF	Demand	Investment	Fiscal Policy	Currency peg	Furlough	Commercial paper	Credit crunch	APR
6	Interest on reserves	Inflation	Economic Growth	Marginal propensity to consume	Income tax	Devaluation	Gig economy	Credit Default Swap	Disintermediation	Arbitrage
7	Interest Rate	Inflation measures	Excess Demand	Reinvestment	Indirect taxation	Exchange Rate	Job Retention Scheme	Debt Ratio	Financial Stability	Coronavirus
8	Loosen	Inflation targeting	Excess Supply	Retail sales	Laffer curve	Exports	Labour	Debt Service Coverage Ratio	Financial System	Covid
9	Market Implied	Inflationary	GDP	Small and Medium Sized Enterprises	Marginal tax rate	Floating exchange rate	Labour market flexibility	Debt to Equity	Fixed rate mortgage	Covid 19
10	Monetarism	Inflationary pressures	GNI	SME	Nash Equilibrium	Imports	Lump of labour fallacy	Derivatives	Flexible mortgage	Crowding out
11	Monetary Policy	Phillips Curve	GNP	Term Funding Scheme	National debt	Japanese Yen	Nairu	Diversification	Gross Profit	Demand Curve
12	Money supply	Price elasticity	Gross Domestic Product	TFSME	Regressive tax	Tradable	Natural rate of unemployment	Dividend Yield	Gross Profit Margin	Demand Elasticity
13	MPC	Reflation	Gross National Income		Regressive taxes	Trade Deficit	Non Accelerating Inflation Rate of Unemployment	Equity	Interest only mortgage	Duopoly
14	Negative interest rates	RPI	Gross National Product		Seigniorage	Trade Surplus	Reservation wage	Equity derivatives	Investment banks	Econometrics
15	Nominal interest rates	RPIX	Industrial output		Tax		Structural unemployment	Finance	Leverage	Economies of Scale
16	Open Market Operations	Stagflation	Lean manufacturing		Taxation		Unemployment	Financial markets	Leverage Ratio	Elasticity
17	QE	Sticky prices	Macroeconomics				Unemployment Rate	Fixed Income	Liability	Endogenous growth theory
18	QT	Wage price spiral	Macroeconomy				Wage price spiral	Fixed Income Security	Liquid asset	Equilibrium
19	Quantitative Easing		Manufacturing output					Foreign direct investment	Liquidity	Externality
20	Quantitative tightening		Marginal cost					Foreign exchange	Liquidity Coverage Ratio	Free rider
21	R*		National income					Foreign exchange market	Liquidity Ratio	Game Theory
22	Real interest rate		Output					Foreign exchange reserves	Loan to value	Geometric Mean
23	Reserves		Output gap					Forex	Loan To Value Ratio	Gini coefficient
24	Taylor rule		PMI					Forward exchange rate	Macroprudential regulation	Gini Index
25	Tighten		Purchasing Managers' Index					Futures Curves	Margin	Gold standard
26	Zero interest rates		Real Gross Domestic Product					Futures Prices	Net Income	Industrial policy
27	Zero lower bound		Slack					Gilts	Net Operating Income	Inequality
28	ZLB		Stagnation					Government Bond	Net Present Value	Informal economy
29			Supply					Hedge	Net Profit Margin	Invisible Hand
30			Supply shock					Hedging	Net Worth	J Curve
31			Supply side economics					Inverted Yield Curve	Non Financial	Joint Probability

B.2 Text Mining

In this section, we explain the specific methods that we used to mine the text from each of the BoE's Monetary Policy Report, Monetary Policy Summary, and Visual Summary publications. The benefit of doing so is that future work might be able to replicate these methods. In addition, this is a fairly arduous task and future research may benefit from a discussion of the methods used to go alongside the code that we will make available.

The Monetary Policy Report (MPR) and Monetary Policy Summaries (MPS) are each found within a single PDF document, whilst the Visual Summary (VS) is available on a BoE web page. Each require different methods to correctly mine the text. We start with the methods used to mine the MPR and MPS text, before subsequently describing that used for the VS.

B.2.1 Monetary Policy Report and Monetary Policy Summary

The first step to mining text is to import text in its raw form. The text for the BoE's Monetary Policy Reports (or 'Inflation Report', up to 2019) and Monetary Policy Summaries are available to download from the quarterly Monetary Policy Report PDF. Raw text imported from a PDF document does not distinguish between text that is within graphs, tables, charts and figures from that that actually makes up the main text. Only the latter is desired. This poses a challenge because, up until 2019 Q3, the structure of the MPR is such that each page of the PDF is split into two columns. On the left hand side (LHS) of each page are the graphs, tables, charts and figures, whilst the main text is located on the right hand side (RHS). Unfortunately, importing the raw PDF text combines the graph/chart text on a line on the LHS with the main text on the same line on the RHS. That is, each raw text line/string is made up of the LHS graph text transitioning seamlessly into the RHS main text. Thus, one major challenge of scraping the document for the relevant main text is distinguishing between the LHS and the RHS text.

In addition, the structure of the text within each document is fairly inconsistent. Specifically, a major challenge is to differentiate between different types of pages, each requiring a different scraper to mine the raw text cleanly. Up to Q3 2019 there are five primary different types of page within each MPR PDF that have to be distinguished between.[53]

1. Title, Contents, Index, and Glossary pages
2. Monetary Policy Summary (MPS) pages
3. MPR 'main' text pages
4. MPR Box text pages
5. MPR 'main' text and Box text combined pages (only present pre-February 2019)[54]

Having downloaded the PDF and imported the raw text into the software used to mine the text (in R), the first task is to split the document text into more manageable chunks, for instance, by page. For the purposes of this analysis, we remove the title, contents, index and glossary pages from each document, focusing on the text for each of the MPS, MPR 'main' text and MPR Box text pages respectively. we now discuss the methods used to mine each of these types of pages. Figures B.1, B.2, B.3, and B.4 show examples of each type of page as well as a snapshot of the cleaned text version of that page from the set of text data constructed.

MPS Text Cleaning

We identify a page as being the first page of the MPS if: the second line on the page contains Monetary

[53] There has been a structural change in the, renamed, 'Monetary Policy Report' in 2019 Q4 which we discuss later on.

[54] Henceforth, we drop the single inverted comma when referring to 'main' text pages.

Policy Summary (lower case pre-Q4 2015); or if the subsequent page is not a Section Title MPR main text page. Unlike MPR main text pages, the MPS text is not split into two columns and contains no graphs, figures, charts or tables and so is relatively straightforward to mine. We omit the title of the MPS from the text string itself across each document, as we also do for the MPR text pages and VS documents.

MPR Main Text Page Cleaning

An MPR main text page is identified as any page that contains any one of the following: a section title; an MPR main text specific chart, table or figure; no MPR Box text specific chart, table or figure; or 5 or more strings in a row that begin with more than one space character (indicating a LHS and RHS column split specific to MPR 'main' text pages). Within each MPR main text page there are a number of further distinctions to be made between different types of pages: section title pages, non-section title pages and pages solely containing a full page table or chart. The latter we remove. Section title pages contain the following: the section title in the second line (sometimes extending to the third), a summary paragraph (sometimes in bullet point format) which spans the width of the page, followed by the bulk of the text which is then split into the LHS and RHS columns. we identify the location of the final line of the summary paragraph, splitting the subsequent lines on the page into a LHS and RHS. In order to be able split lines to reflect the break between the LHS and RHS columns one must first identify the length of the LHS string. This is done by identifying the location of the last character preceding a set of at least 15 space characters. This set of at least 15 space characters represents the break between the LHS and RHS column. The length of the LHS column is different on each page so this process must be characterised generally to work for all pages.

We have kept only the narrative text where possible. Thus, we discard each of the following: text on the LHS column of each page (associated with charts, tables, graphs or figures, headers at the top of each page, footnotes at the bottom of each page and sources. We also remove the actual section title and subsection titles from the text string. We do this for consistency with previous sets of such text data (Haldane and McMahon, 2018). In addition, we remove the bullet points from each of the section 'summaries' and add full stops at the end of each to ensure that they are regarded as separate sentences when it comes to applying the measures of linguistic complexity.

MPR Box Text Page Cleaning

Firstly, we identify a Box page as any page that contains: box specific charts, tables, figures, or graphs (these have a slightly different title structure to those in the main text pages); or a lines containing a '?' (subheadings phrased as questions are unique to boxes). Similarly to the main text pages, the Box text pages are split into a LHS and RHS column. we identify the length of the LHS string for each Box page using the same method as above. Unlike main text pages, however, there is no such systematic split of charts and figures on the LHS and text on the RHS. Instead, charts, figures, and text are all intermingled. Hence, for each box page we separate the chart, figure and table lines from the text by identifying and removing lines that contain the following: box specific chart, figure, graph or table title and all of the subsequent 5 lines, begin with more than 2 space characters, begin with 'Source' and all of the subsequent 4 lines, begin with '(X)' where X is a number (reflecting a specific source is being given for that chart, table graph or figure), or begin with 'Key Judgment'. Similarly to the main text pages, we remove the title of the Box, again consistent with previous work by Haldane & McMahon (2018), and also remove any footers at the bottom of the RHS. This leaves just the Box text of interest.

Mixed MPR main and Box Text Page Cleaning

Up to the Q1 2019 MPR, Boxes are not exclusively confined to their own pages and no longer located exclusively at the end of a section. Instead, they are commonly intermingled with 'main' text appearing in the middle of a section as opposed to the end. We identify a page as being a mixed MPR main and Box text page if it contains any of the following: both a main page specific and a Box page specific chart, table, figure or graph; or any of the other conditions unique to both main and Box text pages

respectively.

One then needs to separate the Box text from the main text and and run the appropriate code (described above) on the respective sections of the page. Thankfully, Box text always comes at the top of the page with the 'main' text below it. Thus, one can identify the first line of the main text by identifying the first line on the page to contain either: a 'main' text specific chart, table, graph or figure; or at least 3 consecutive lines of no text on the LHS column. Having identified where the Box ends and the 'main' text begins one can direct the different sections to the relevant parts of the code that scrape that style of page.

Looped script for all documents
Having tailored our code to correctly scrape each page for all the different possible formats of text structure of the MPR publications, we loop this code to run on all pages of each MPR document from Q3 2015 to Q3 2019. The above methods are exhaustive and work for every page in every document during this time period.

There was a systematic change in the text structure of the MPR in Q4 2019. Specifically, the document no longer splits main and Box text pages into a LHS and RHS column. This makes the document substantially more simple to mine for the relevant text data, but requires a different scraper to do so. Hence, Q4 2019 onwards, we use a slightly modified algorithm to mine the text. However, we have made this as general as possible and will be replicable for future Monetary Policy Reports, absent any further significant structural changes.

All of this text data has been saved in a single data frame, readily available for future analysis.

Novel Data Set
Having mined the relevant text from the MPR publications as described above, we have collated this data into a single data frame. This data frame contains separate columns for each of: MPR main text, MPR Box text, and MPS text. This segmentation allows for analysis to be conducted on each either separately or jointly however is preferred. Specifically, each cell within any one of the columns stated above contains a page of text in a single character string. Columns stating the document, page number, section, subsection, or box to which this text data belongs run alongside the cells containing the text data for chronological purposes.

B.2.2 Visual Summaries

The Visual Summary text is significantly more straight forward to scrape. The Visual Summaries are each available on a URL web page, as opposed to solely in PDF form as is the case for the Inflation Reports. Using the in-built Google Chrome tool 'Selector Gadget' one can select the sections of the web page containing the relevant text to import. Thus, by the time the raw text has been imported into R, it is fairly clean already. The relevant text that we restrict our analysis to is: the interest rate rise, the four key summary points at the top of the page, the subsequent sub-headings and corresponding text. That is, we omit chart text, chart titles, related links, sources and the title (for consistency with the MPS and MPR text data).

The text data for the Visual Summaries lies in a separate data frame, with each cell in the text column containing all of the (cleaned) text from a single VS page in a single character string. Figure B.5 shows an example of a VS page and the text mined from it.

Monetary Policy Summary

The Bank of England's Monetary Policy Committee (MPC) sets monetary policy to meet the 2% inflation target, and in a way that helps to sustain growth and employment. At its meeting ending on 31 July 2019, the MPC voted unanimously to maintain Bank Rate at 0.75%. The Committee voted unanimously to maintain the stock of sterling non-financial investment-grade corporate bond purchases, financed by the issuance of central bank reserves, at £10 billion. The Committee also voted unanimously to maintain the stock of UK government bond purchases, financed by the issuance of central bank reserves, at £435 billion.

Since May, global trade tensions have intensified and global activity has remained soft. This has led to a substantial decline in advanced economies' forward interest rates and a material loosening in financial conditions, including in the United Kingdom. An increase in the perceived likelihood of a no-deal Brexit has further lowered UK interest rates and led to a marked depreciation of the sterling exchange rate.

Brexit-related developments, such as stockbuilding ahead of previous deadlines, are making UK data volatile. After growing by 0.5% in 2019 Q1, GDP is expected to have been flat in Q2, slightly weaker than anticipated in May. Looking through recent volatility, underlying growth appears to have slowed since 2018 to a rate below potential, reflecting both the impact of intensifying Brexit-related uncertainties on business investment and weaker global growth on net trade. Evidence from companies, up to the middle of July, suggests that uncertainty over the United Kingdom's future trading relationship with the European Union has become more entrenched. The labour market remains tight. Annual pay growth has been relatively strong. Consumer spending has remained resilient. CPI inflation was 2.0% in June and core CPI inflation was 1.8%.

The Committee's updated projections are set out in the accompanying August *Inflation Report*. They continue to assume a smooth adjustment to the average of a range of possible outcomes for the United Kingdom's eventual trading relationship with the European Union. In the central projection, conditioned on prevailing asset prices, underlying output growth is subdued in the near term, reflecting more entrenched Brexit uncertainties. This means that a margin of excess supply persists over the first year of the projection. Thereafter, GDP is projected to accelerate to robust growth rates, reflecting a gradual recovery in global growth and firming UK domestic demand growth, driven in large part by a recovery in investment growth as uncertainties dissipate in line with the Brexit conditioning assumption. The acceleration in GDP results in a significant build-up of excess demand, to around 1¾% of potential GDP by the end of the forecast period. After falling in the near term, CPI inflation is projected to rise above the 2% target, as building excess demand leads to firmer domestic inflationary pressures. Conditioned on prevailing asset prices, CPI inflation reaches 2.4% by the end of the three-year forecast period.

These projections are affected by an inconsistency between the smooth Brexit conditioning assumption underpinning the forecast and the prevailing market asset prices on which the forecasts are also conditioned. These asset prices reflect market participants' perceptions of the likelihood and consequences of a no-deal Brexit. If, as assumed, Brexit proceeds smoothly to some form of deal, market interest rates would likely rise and the sterling exchange rate would likely appreciate. A more consistent forecast would therefore have somewhat lower paths for GDP growth and CPI inflation.

Figure B.1: Monetary Policy Summary example page and cleaned text data

1 Global developments and domestic financial conditions

- The outlook for global growth has deteriorated a little, in part reflecting escalating trade tensions.
- The market path for interest rates has fallen further in the UK since May, as in other advanced economies.
- The probability market participants attach to a no-deal Brexit has increased. This has contributed to the lower path for UK interest rates and the 4% depreciation of sterling.

(a) Measures of current monthly composite (services and manufacturing) output, manufacturing output, and manufacturing export orders growth based on the results of surveys in 44 countries. Together these countries account for an estimated 89% of global GDP.

1.1 Global economic developments

Since May, the outlook for global growth has deteriorated a little. In 2019 Q2, UK-weighted world GDP growth appears to have slowed slightly to 0.4% (**Table 1.A**), slightly lower than expected in May. US and euro-area GDP growth both slowed, following surprising strength in Q1, to 0.5% and 0.2% respectively. Growth in emerging markets has been weaker than projected in the May *Report*, having slowed in the past year reflecting a previous tightening in financial conditions.

Higher-frequency indicators further suggest that global output growth may have weakened in recent months. Global PMIs have continued to fall since May, particularly in the manufacturing sector, where the output index has dipped below 50 (**Chart 1.1**). Forward-looking surveys suggest that growth is likely to stabilise in the near term. For example, the manufacturing export orders index has remained at a similar level over the past three months (**Chart 1.1**).

Softer global growth — particularly in the manufacturing sector — is likely at least in part to reflect the impact of trade tensions, which have increased over the past year and intensified further since May. The US and China both implemented higher tariffs over 2018, with the US applying tariffs to US$250 billion of imports from China, and China reciprocating with tariffs on US$110 billion of imports from the US. Tariffs were due to increase in 2019, but at the time of the May *Report*, those were not assumed to be implemented, given that trade talks between the two countries appeared to be progressing positively. Trade talks subsequently broke down, however, and tariffs were increased.

As well as the tariffs implemented so far, other developments have added to concerns about trade protectionism. For example, the US announced plans to impose further tariffs on all remaining imports from China, although in June both parties agreed to continue talks. The US administration is also

Figure B.2: Monetary Policy Report main text example page and cleaned text data

Box 2
Agents' update on business conditions

The key information from Agents' contacts considered by the Monetary Policy Committee at its August meeting is highlighted in this box.(1)

Recent developments

Activity had slowed in the past three months compared with a year ago, particularly in manufacturing and construction.(2) Most of that was due to temporary factors, but it also partly reflected weaker underlying growth.

The Agents' scores for manufacturing output and exports were their lowest in almost three years. This partly reflected one-off effects from an unwinding of stockbuilding and shutdowns in car production that had been brought forward from the summer. Nonetheless, there were also signs of weaker underlying demand for exports as global growth had slowed.

Construction sector activity contracted, as major infrastructure projects had been put on hold and house-building activity had eased.

Business services growth was modestly weaker, reflecting depressed demand for financial, corporate advisory and hospitality services. Part of that could be due to Brexit-related uncertainty. However, demand for logistics and IT services remained buoyant.

Agents' survey on preparations for EU withdrawal

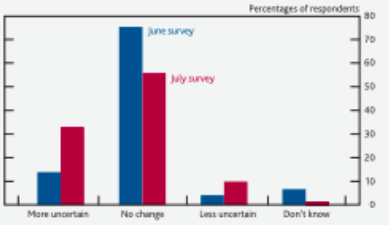

The Agents surveyed over 300 business contacts on their preparations for EU withdrawal — the sixth vintage of the survey to date.(3)

In the latest survey, about a third of respondents reported being more uncertain about the economic outlook now than they had been prior to the extension of the EU withdrawal deadline — around double the proportion that answered that way in the June survey (**Chart A**). Just over half of respondents reported no change in uncertainty, down from three quarters of respondents in the June survey.

When asked about their contingency plans for Brexit, almost 90% of respondents said that they had implemented contingency plans ahead of the March withdrawal deadline (**Chart B**).

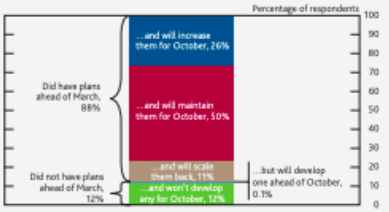

Half of respondents said they would maintain the plans they had in March and a quarter of companies said they would increase planning. A small proportion of companies said that they would scale back previous plans, but discussions with contacts suggested that most of those expected to reintroduce plans ahead of the EU withdrawal deadline on 31 October.

Chart A Companies are more uncertain about the outlook
Change in uncertainty since the Brexit deadline extension(a)

(a) Companies were asked 'Are you more or less uncertain about the economic outlook now than you were prior to the extension of the EU withdrawal deadline to the end of October 2019?'.

Chart B Most companies have contingency plans for Brexit
Brexit contingency plans(a)

(a) Companies were asked 'How has the Brexit extension affected your contingency plans?'. Bars may not sum to 100 due to rounding.

Asked about their readiness for a no-deal Brexit, three quarters of respondents said that they considered themselves 'as ready as they can be', and just under a fifth described themselves as 'fully ready'. This was similar to the June survey.

Authorities have taken steps to improve the preparedness of the real economy for a disorderly Brexit. The UK has announced Transitional Simplified Procedures for customs checks at the border and a temporary waiver on security checks. The Port of Calais and Eurotunnel announced that they have completed their preparations on French border infrastructure. Agreements have been signed to roll over existing EU trade deals with the rest of the world representing about 5½% of the UK's total goods trade.

(1) A comprehensive quarterly report from the Agents on business conditions is published alongside the MPC decision in non-*Inflation Report* months. The next report will be published on 19 September 2019.
(2) This is a summary of economic reports compiled by the Agents during June and early July 2019. References to activity and prices relate to the past three months compared with a year earlier. The Agents' scores are available here.
(3) The survey was conducted between 17 June and 5 July. There were 318 responses from companies employing over 500,000 employees. Responses were weighted by employment and then reweighted by sector employment.

Figure B.3: Example of Monetary Policy Report Box text page and cleaned text data

Box 1
Monetary policy since the February *Report*

In the MPC's central projection in the February *Report*, GDP was expected to grow by around 1¾% per year on average over the forecast period. While modest by historical standards, that growth rate was expected to exceed the diminished rate of supply growth of the economy, which was projected to be around 1½% per year. As a result, a small margin of excess demand was projected to emerge by early 2020 and build thereafter. That would support domestic cost growth, although CPI inflation was projected to fall back gradually as the effects of sterling's past depreciation faded. Conditional on the path for Bank Rate implied by market interest rates prevailing at the time, inflation remained above the 2% target in the second and third years of the MPC's central projection.

At its meeting ending on 21 March 2018, the MPC noted that recent data releases had been broadly consistent with the view of the medium-term outlook set out in the February *Report*. The prospects for global GDP growth remained strong, and financial conditions continued to be accommodative, with little persistent effect from the recent financial market volatility.

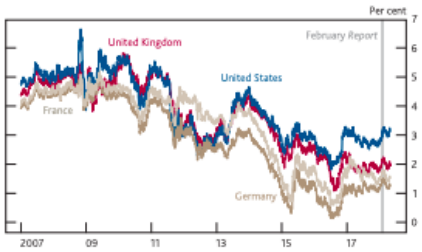

CPI inflation fell from 3.0% in January to 2.7% in February. Inflation was expected to ease further, although to remain above the 2% target in the short term. A range of measures of domestically generated inflation had picked up, although they generally remained below target-consistent levels. Wage growth had also increased steadily, as expected. The unemployment rate had remained low and other indicators suggested that the margin of spare capacity within the labour market was limited. Taken together with the increase in job-to-job flow rates, which could strengthen workers' bargaining power, this provided increasing confidence that growth in wages and unit labour costs would pick up to rates consistent with the inflation target.

As in February, the best collective judgement of the MPC remained that, given the prospect of excess demand, an ongoing tightening of monetary policy over the forecast period would be appropriate to return inflation sustainably to its target at a more conventional horizon. All members agreed that any future increases in Bank Rate were likely to be at a gradual pace and to a limited extent.

For seven members, however, that did not require an increase in Bank Rate at this meeting. There had been few surprises in recent economic data and the February *Inflation Report* projections, conditioned on a gently rising path of Bank Rate, had appeared broadly on track. The May forecast round would enable the Committee to undertake a fuller assessment of the underlying momentum in the economy, the degree of slack remaining and the extent of domestic inflationary pressures.

Two members favoured a rise in Bank Rate by 25 basis points. They noted the widespread evidence that slack was largely used up and that pay growth was picking up, presenting upside risks to inflation in the medium term. A modest tightening of monetary policy at this meeting could mitigate the risks from a more sustained period of above-target inflation that might ultimately necessitate a more abrupt change in policy.

between lenders in the face of subdued demand for credit in the UK.

Borrowing costs for households and companies are projected to rise gradually further in coming years. The market-implied path for Bank Rate remains upward sloping and bank funding costs, over and above those market rates, have risen in recent months, unwinding some of the compression since 2016. This will feed through gradually to higher retail interest rates. Nevertheless, credit conditions are likely to remain accommodative, and this will support the outlook for consumption and business investment (Section 5).

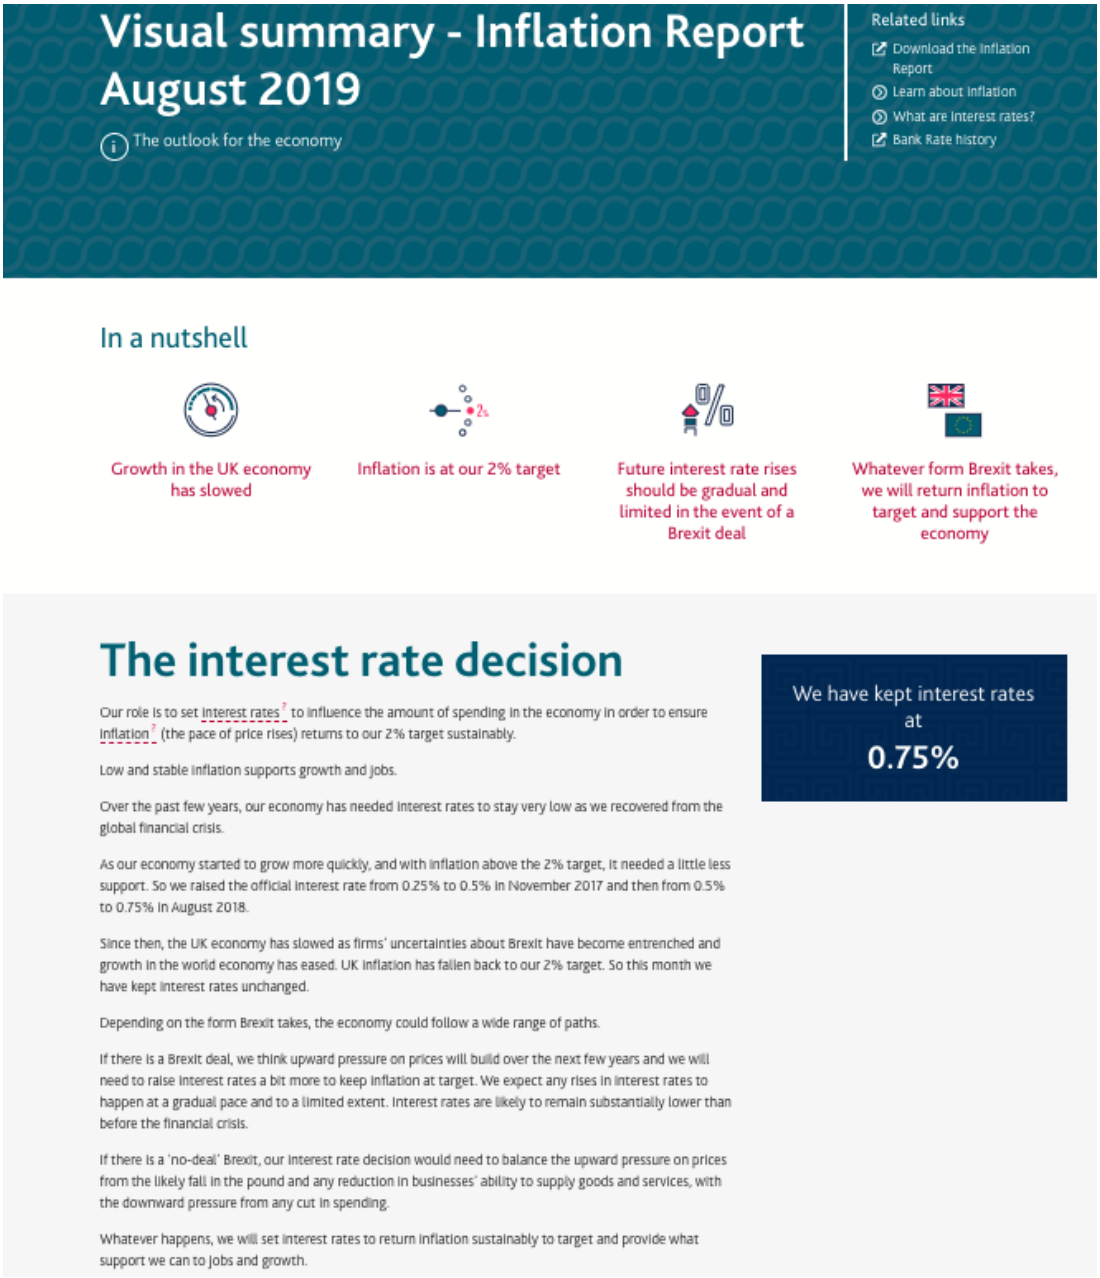

Bank funding costs and retail deposit rates

This will feed through gradually to higher retail interest rates. Nevertheless, credit conditions are likely to remain accommodative, and this will support the outlook for consumption and business investment (Section 5). Bank funding costs and retail deposit rates As explained in Box 2, an important component of the interest rates facing households and companies is the cost of bank funding. During the financial crisis, the spread between reference rates and bank funding costs rose sharply as investors demanded higher compensation for the risks associated with providing funding to banks (Chart 1.11). These	Box 1.	Monetary policy since the February Report. In the MPC's central projection in the February Report, GDP was expected to grow by around 1¾% per year on average over the forecast period. Figure B.4: Example of Monetary Policy Report combined 'main' and Box text page and cleaned text data

(i) Example: A section of the 2019 Q3 VS

Quarter	Visual_Summary
2019_Q3	In a nutshell. Growth in the UK economy has slowed. Inflation is at our 2% target. Future interest rate rises should be gradual and limited in the event of a Brexit deal. Whatever form Brexit takes, we will return inflation to target and support the economy. The interest rate decision. Our role is to set interest rates to influence the amount of spending in the economy in order to ensure inflation (the pace of price rises) returns to our 2% target sustainably. Low and stable inflation supports growth and jobs. Over the past few years, our economy has needed interest rates to stay very low as we recovered from the global financial crisis. As our economy started to grow more quickly, and with inflation above the 2% target, it needed a little less support. So we raised the official interest rate from 0.25% to 0.5% in November 2017 and then from 0.5% to 0.75% in August 2018. Since then, the UK economy has slowed as firms' uncertainties about Brexit have become entrenched and growth in the world economy has eased. UK inflation has fallen back to our 2% target. So this month we have kept interest rates unchanged. Depending on the form Brexit takes, the economy could follow a wide range of paths. If there is a Brexit deal, we think upward pressure on prices will build over the next few years and we will need to raise interest rates a bit more to keep inflation at target. We expect any rises in interest rates to happen at a gradual pace and to a limited extent. Interest rates are likely to remain substantially lower than before the financial crisis. If there is a 'no-deal' Brexit, our interest rate decision would need to balance the upward pressure on prices from the likely fall in the pound and any reduction in businesses' ability to supply goods and services, with the downward pressure from any cut in spending. Whatever happens, we will set interest rates to return inflation sustainably to target and provide what support we can to jobs and growth. Whatever form Brexit takes, we will return inflation to target and support the economy.

B.2.3 Summary Statistics for BoE Publications

Table B.1: Summary statistics of the linguistic complexity measures

Linguistic Complexity Measure	Type*	Obs	Mean	Std. Dev	Min	Max
Word Count†	MPR	71	20,730	2,273	15,963	27,336
	MPS	32	997	226	618	1,474
	VS	23	950	258	566	1,558
Flesch-Kincaid	MPR	71	12.67	1.30	9.93	15.22
	MPS	32	13.31	0.89	11.84	15.46
	VS	23	6.30	0.88	4.79	8.62
Proportion of Jargon (%)	MPR	71	5.56	0.44	4.45	6.27
	MPS	32	8.95	1.12	6.68	10.68
	VS	23	5.82	1.08	3.89	8.48
Conceptual Complexity Index (CCI) (%)	MPR	71	17.64	2.44	12.67	23.98
	MPS	32	26.44	3.52	19.21	34.46
	VS	23	9.76	2.06	5.56	13.56

*Type represents Bank of England Publication Type. † Statistics reported to 0 decimal places. The remaining statistics are reported to 2 decimal places.

Table B.2: Complexity vs Psychological and Social metrics based on LICW 2015

	Complexity metrics				Social and Psychological metrics		
Text	**CC**	**SC**	**PJ**	**CCI**	**Analytic**	**Authentic**	**Tone**
1	Low	Low	5	10	91.5	67.1	66.7
2	Low	Medium	5	10	91.1	68.8	69.8
3	Medium	Low	10	15	89.1	65.9	52.4
4	Medium	Medium	10	15	89.6	67.7	56.3
5	High	High	10	30	98.8	31.1	33.5
6	High	High	10	30	99.0	37.2	33.5

B.2.4 Word Cloud for MPR

Figure B.6: Word Cloud for MPR (2005-2023)

Note: This figure presents word clouds based on the full corpus of text in the MP Report 2005-2023. The size of each word reflects the number of instances that it was referenced in each document across the respective periods. Blue words are 'jargon' terms. The 'stem' of the word is reported in these clouds, rather than the full word, such that, for instance, words like 'committee' and 'committees' are identified as the same term.

Figure B.7a: Word Cloud of jargon terms

(i) MP Summary (2015-2023)

(ii) Visual Summary (2017-2023)

Note: This figure presents word clouds based on the full corpus of text in the MP Summary 2015-2023 (left-hand side) and the Visual Summary 2017-2023 (right-hand side). The size of each word reflects the number of instances that it was referenced in each document across the respective periods. The colour represents whether a word is a 'jargon' term, with red used for jargon terms in the MP Summary, and green for those in the Visual Summary). The size of the cloud itself reflects the number of distinct words used in each document, with a larger cloud signifying a greater number of different words. The 'stem' of the word is reported in these clouds, rather than the full word, such that, for instance, words like 'committee' and 'committees' are identified as the same term.

Figure B.7b: Word Cloud of jargon terms

(i) MP Summary 2019 Q4

(ii) MP Summary 2023 Q2

Note: This figure presents word clouds based on the text corpus for the MP Summary 2019 Q4 (left-hand side) and MP Summary 2023 Q2 (right-hand side). The interpretation of words' size and colour, and the size of the cloud itself is as described in the subfigure above.

Appendix C Descriptive and summary statistics

C.1 Pre-treatment characteristics

Table C.1: Descriptive statistics: pre-treatment priors across demographic groups

		Inflation Target			Who sets rates?	Understand BoE	Trust BoE	Keep up to date
Group	N	Mean	SD	Median	Prop. Correct	Mean	Mean	Mean
All	1859	6.66	3.00	16.88	0.58	3.34	3.14	1.60
Gender								
Female	1194	7.75	4.00	17.48	0.51	3.23	3.13	1.45
Male	632	4.34	2.00	13.36	0.69	3.52	3.16	1.88
Country of Birth								
Born outside of UK	373	6.49	3.00	18.51	0.54	3.25	3.03	1.61
Born in UK	1486	6.70	3.00	16.45	0.58	3.36	3.17	1.60
Income Group								
£1 - £9,999	369	9.34	4.00	18.97	0.46	3.26	2.98	1.35
£10,000 - £25,000	623	7.91	4.00	18.74	0.51	3.31	3.09	1.53
£25,000 - £49,999	568	4.62	2.50	13.16	0.69	3.34	3.25	1.77
£50,000 - £75,000	103	3.41	2.00	9.27	0.79	3.78	3.58	2.23
>£75,000	41	2.61	2.00	10.23	0.88	4.05	3.51	2.30
Education level								
Secondary school or less	266	10.37	5.00	18.76	0.47	3.18	3.06	1.43
Some post-school Education	427	8.49	5.00	18.63	0.50	3.36	3.10	1.46
Professional Degree	81	3.83	2.00	13.99	0.77	3.62	3.23	1.97
University Degree	741	6.04	3.00	15.85	0.60	3.34	3.16	1.62
Master's Degree	281	4.83	2.00	16.01	0.66	3.41	3.19	1.79
Doctorate Degree	63	2.84	2.00	8.37	0.68	3.17	3.22	1.73
Has studied Economics?								
Did not study Economics	1559	6.96	3.00	17.12	0.56	3.27	3.11	1.53
Studied Economics	300	5.02	2.00	15.41	0.68	3.69	3.30	1.97

Note: This table reports descriptive statistics on responses to pre-treatment questions eliciting respondents' understanding of, and trust and interest in, macroeconomics and monetary policy across demographic groups. We report respondents' mean, median, and standard deviation of responses to a question asking what the inflation target is of the UK authority in charge of interest rates (correct answer is 2%). To calculate the mean value, we winsorize the distribution to exclude the top 5% of responses, given the presence of a long right-hand tail. We also report the proportion of respondents in each group who correctly responded that either 'Bank of England' or 'Monetary Policy Committee' sets interest rates in the UK. 'Understand BoE' is a categorical variable ranging from 1 (low) to 5 (high) capturing respondents' self-reported understanding of the BoE's role prior to the study. 'Trust BoE' and 'Keep up to date' are similarly categorical variables ranging from 1 (low) to 5 (high) capturing respondents' self-reported trust in the BoE, and the degree to which they keep up to date with te state of the economy, respectively.

C.2 Randomisation across Treatments

C.2.1 Summary Statistics

Table C.2: Summary statistics across treatments

(a) Demographic characteristics

		Age		Male (%)		Born in UK (%)		Income (1-7)		Education (1-8)		Econ at Uni (%)

C.2.2 Balance Tests

To perform balance tests across the treatment arms, empirically test for systematic differences in demographic characteristics and pre-treatment priors across treatments by running the following regression specification:

$$\mathrm{X}_i = \gamma_1 + \gamma_k' \mathrm{Text}_{k,i} + \epsilon_i \tag{37}$$

where X_i represent demographic characteristics and pre-treatment priors of interest, for individual i. $\mathrm{Text}_{k,i} = \begin{pmatrix} \mathrm{Text}_{2,i} & \mathrm{Text}_{3,i} & \mathrm{Text}_{4,i} & \mathrm{Text}_{5,i} & \mathrm{Text}_{6,i} \end{pmatrix}'$ represents the information treatment that respondent i is randomly assigned to, with $\gamma_k = \begin{pmatrix} \gamma_2 & \gamma_3 & \gamma_4 & \gamma_5 & \gamma_6 \end{pmatrix}'$ representing the associated estimated coefficient for $k \in \{2, 3, 4, 5, 6\}$. γ_1 is the intercept, which represents the average value for that variable of interest amongst respondents who are randomly assigned to the baseline Text 1 with 'Low' semantic and conceptual complexity, which we use as our 'baseline' treatment. γ_k then represent the marginal difference in that value for each treatment k, relative to the baseline. As in our regression specifications, standard errors on the estimated treatments are adjusted for multiple hypothesis testing, as per the recommendations in List et al. (2019, 2023).

Table C.3: Balance tests across treatments: Demographic characteristics and pre-treatment beliefs (Full Sample)

	Dependent variable:										
	Demographic Characteristics						Pre-treatment priors

Appendix D Further results

D.1 Auxiliary Results

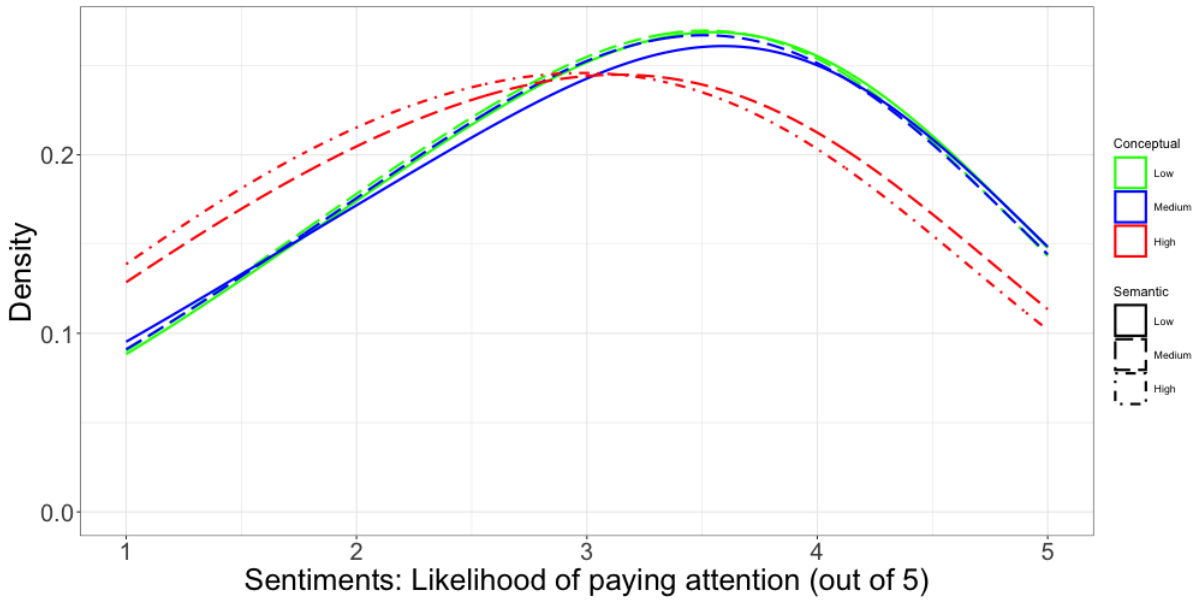

D.1.1 Density plots

Figure D.1a: Density plots: Sentiments: Understanding of BoE's role

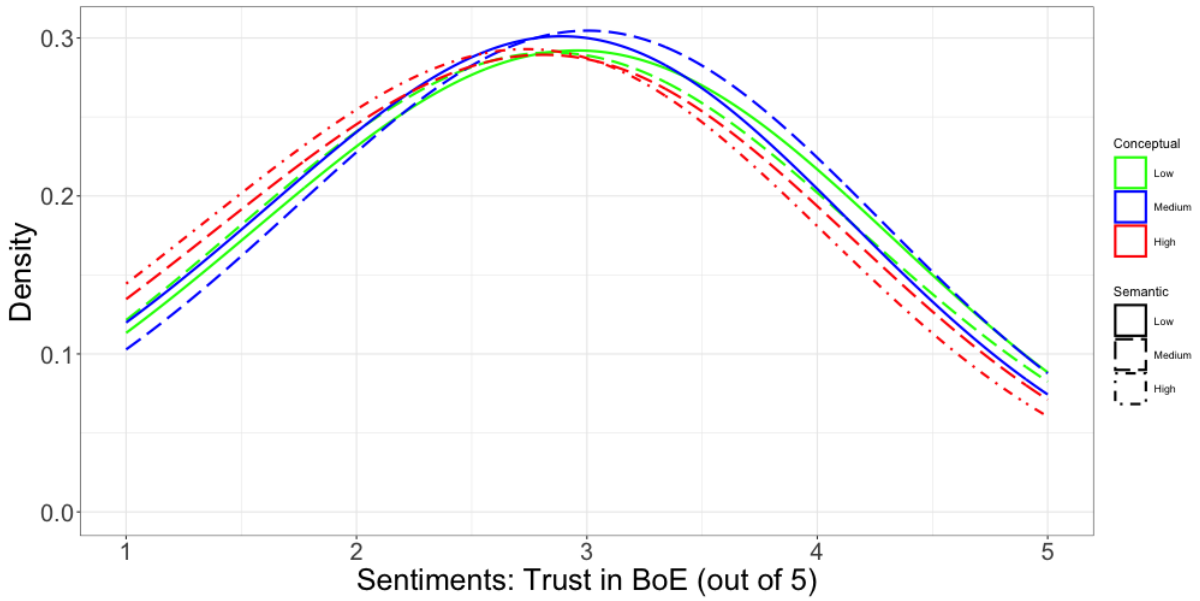

Note: This figure presents the density distribution across treatments that vary in the degree of semantic and conceptual complexity, for responses to Q41: *To what extent do you agree with each of the following statements: Having read the document, I now have a better understanding of the role of the Bank of England*;', with options ranging from (1) *None or nearly none of it*' to '(5) *All or nearly all of it*'.

Figure D.1b: Density plots: Sentiments: Likelihood of paying attention to BoE

Note: This figure presents the density distribution across treatments that vary in the degree of semantic and conceptual complexity, for responses to Q41: *To what extent do you agree with each of the following statements: Having read the document, I am now more likely to pay attention to future documents published by the Bank of England*, with options ranging from '(1) *Disagree Strongly*' to '(5) *Agree Strongly*'.

Figure D.1c: Density plots: Sentiments: Trust in BoE

Note: This figure presents the density distribution across treatments that vary in the degree of semantic and conceptual complexity, for responses to Q41: *To what extent do you agree with each of the following statements: Having read the document, I now have more trust in the Bank of England as an institution*, with options ranging from '(1) *Disagree Strongly*' to '(5) *Agree Strongly*'.

D.1.2 Alternative Specification

We have shown in Table 3 that conceptual complexity reduces people's perceived and actual understanding of information, and sentiments towards the central bank, while semantic complexity does seem to have a significant impact. We can directly compare the relative importance of conceptual and semantic dimensions of complexity by re-specifying our baseline regression model described by Equation 37 to estimate:

$$\begin{aligned} \mathrm{Y}_i = \beta_1 &+ \beta_M^C \text{Conceptual Medium}_i + \beta_H^C \text{Conceptual High}_i \\ &+ \gamma_M^S \text{Semantic Medium}_i + \gamma_H^S \text{Semantic High}_i \\ &+ \delta X_i + \epsilon_i \end{aligned} \tag{38}$$

where Conceptual Medium$_i$, Conceptual High$_i$, Semantic Medium$_i$, and Semantic High$_i$ are dummy variables that take the value of 1 if respondent i is treated with a text of that respective level of complexity, and 0 otherwise. X_i represents the same set of conditioning factors as in Equation 37 and ϵ_i is the error term. This re-specification of Equation 37 allows us to interpret the $\beta_{Level}^{Dimension}$ coefficients as the estimated causal *marginal* effect on Y_i of reading a text of 'Medium' or 'High' complexity $\{\mathrm{M}, \mathrm{H}\}$ across dimensions of 'conceptual' or 'semantic' complexity $\{\mathrm{C}, \mathrm{S}\}$, relative to the baseline Text 1 of 'Low' complexity across both dimensions, conditioning on the level of complexity across the *other* dimension and on demographic factors and pre-treatment informedness.[55] Table D.2 reports the estimated coefficients from the re-specified regression described by Equation 38, across each of our dependent variables of interest.

[55] To note, this re-specification does not allow us to adjust standard errors for multiplicity. However, the empirical results obtained based on the specification described by Equation 37 give us confidence that our findings are not driven by false positives.

Appendix E Media article analysis

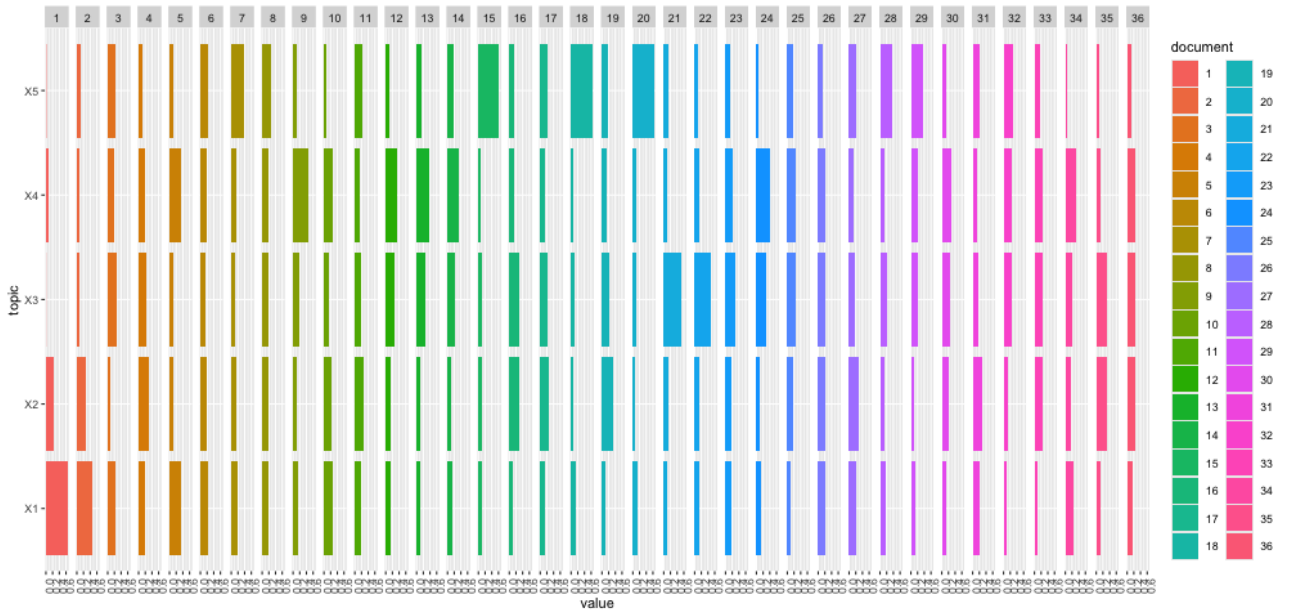

E.1 Identifying topics using LDA

Figure E.3a: Topics identified by LDA: 2016 Q3

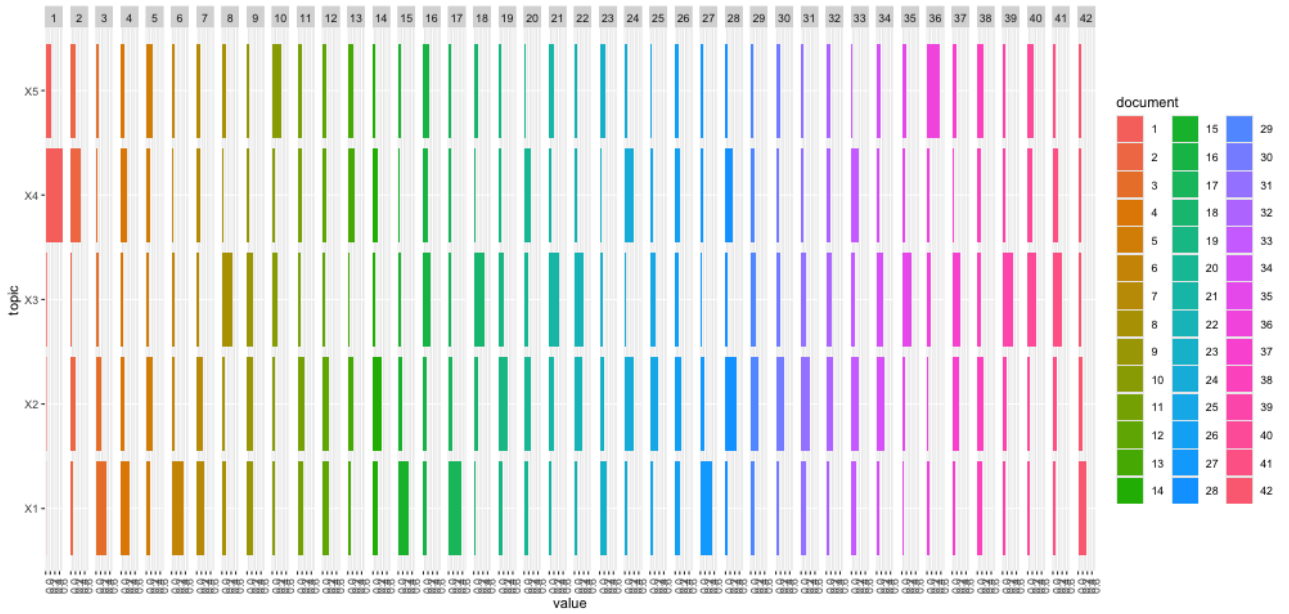

Note: This figure presents the results of the LDA topic model, based on a corpus of text data including all BoE publications and media reports in 2016 Q3. The model identifies five topics (y-axis), and provides the proportion of each report that that cover each of these topics. The first two columns represent the BoE's MPR and MPS respectively, while the remaining columns represent each of the media articles in that period. Based on the topics, we judge Topic 3 as relating to 'political economic' matters. The top 20 key words in each of the five topics identified are:
Topic 1: "inflat term bond lower mpc polici reduc measur target household support purchas provid addit economi effect pass asset fund monetari"
Topic 2: "bank rate scheme interest govern fund borrow central boe money loan packag lend tfs point boost profit direct made grow"
Topic 3: "economi brexit england £bn carney stimulus governor today hammond shock britain monetari polici chancellor economist predict warn quantit step mark"
Topic 4: "price growth fall market expect project demand increas cost sterl reflect suppli compani outlook activ uncertainti remain invest referendum domest"
Topic 5: "cut bank vote growth expect forecast recess low month packag buy record slash policymak econom downgrad quarter programm base biggest"

Figure E.3b: Topics identified by LDA: 2017 Q3

Note: This figure presents the results of the LDA topic model, based on a corpus of text data including all BoE publications and media reports in 2017 Q3. The model identifies five topics (y-axis), and provides the proportion of each report that that cover each of these topics. The first two columns represent the BoE's MPR and MPS respectively, while the remaining columns represent each of the media articles in that period. Based on the topics identified, we judge Topic 3 as that relating to 'political economic' matters. The top 20 key words in each of the five topics identified are:
Topic 1: "price growth project remain import recent period market cost continu fall export past term averag broad product fallen wage increas"
Topic 2: "expect household invest growth rise weak pick quarter demand incom gdp year decis consum uncertainti current report target polici busi"
Topic 3: "bank england carney brexit vote economi governor forecast warn hit cut monetari predict mark inflat britain policymak hold decad member"

Note: This figure presents word clouds of all the jargon terms used in media articles reporting on the BoE interest rate decision in 2017 Q4. The size of the terms represents the frequency of its usage, while the colour of the terms represents whether they also featured in one of the BoE's own publications that quarter – blue for the MPR (left-hand side), red for the MPS (right-hand side).

Appendix F Survey Treatments: CB reports from a hypothetical economy

Figure F.5: Text 1: Low Semantic, Low Conceptual Complexity

In a nutshell. Interest rates kept at 0.5%. The fall in the value of the pound has led to higher prices. The world economy is growing strongly. The squeeze in living standards is easing. Inflation will fall back towards our 2% target.

The economy now needs a little less support. We cut interest rates to exceptionally low levels during the supply crisis to support spending and to reduce the number of people out of work. Over the past few years our economy has needed interest rates to stay very low as we recovered from the global supply crisis. But things are changing. The world economy is now growing strongly. In this country, the share of people without a job is at its lowest level for over 40 years, and businesses are finding it hard to recruit people. Our economy is probably growing about as fast as it can without overheating (at 1.6%). And inflation is above our 2% target (at 3.0%). That means the economy needs a little less support than before. So last quarter, we raised the official interest rate we set, known as Bank Rate, from 0.25% to 0.5% . In this quarter, we have kept it at 0.5%.

Our job is to meet the 2% inflation target. Inflation is currently above that target, because of the big fall in the value of the pound resulting from the trade war. The weaker pound has meant that things businesses get from abroad cost more. Businesses will need to pass those rising costs on to their customers. So that has meant higher prices in the shops. The fall in the value of the pound happened around 18 months ago. Its effect on inflation doesn't last forever. And in the next few months inflation is going to start to fall back gradually towards our target.

Just like at home, the world economy had been quite weak following the supply crisis. But across Europe, in the US and many other countries the economy is now growing strongly. Stronger growth abroad will benefit our economy by increasing demand for our exports. And it should encourage companies to invest and recruit more staff to meet this extra demand.

Over the past year, prices have been rising faster than wages. That means people have not been able to afford as much. We think that is changing. The share of people out of work is now at its lowest level since 1975. And there are a lot of job vacancies. This means that companies are having to compete hard with each other to recruit and retain workers. One way they do that is by offering higher wages – so we expect bigger pay rises over the next few years. We think that pay will rise faster than prices this year, easing the squeeze on living standards.

To make sure inflation falls back to our 2% target, we need to set interest rates (the cost of borrowing) so that the amount of spending in the economy isn't too low or too high. If we set interest rates too low, then growth in the economy will be too fast, and inflation will stay above our target. But if we set interest rates too high or raise them too rapidly then growth will be too slow, and inflation will fall below our target. Put another way, we need to keep the economy growing at its speed limit. The speed limit for the economy is determined by two things: how many people are in work; and how productive the businesses they work for are. A few years ago many more people were out of work. So there was scope for the economy to grow quite quickly as a lot of those people found jobs. Now, with a record number of people in work, there isn't much more economic growth that can come from unemployed people finding work. Instead, it will mostly need to come from higher productivity - our ability to produce more with the people already in work and the resources that we have. But productivity has barely risen over the past decade. And we think that productivity will probably grow relatively slowly in coming years, too. We think that for inflation to settle back at the 2% target, the economy probably needs to grow at around 1.5% in coming years.

Inflation has been above our 2% target over the past year because of the sharp fall in the pound triggered by the trade war. During that time, we had to balance how quickly we take inflation back to the target with the support we give to jobs and activity. To ensure a sustainable return of inflation to the target, we need to keep economic growth around its new, lower, speed limit. With a strengthening world economy and more people in work, our economy now needs a little less support from us. We raised interest rates last quarter from 0.25% to 0.5%. If the economy continues to perform as expected, we think we will need to raise them further, reducing the amount of support we are providing to the economy. We expect any further rises in interest rates to happen at a gradual pace and to a limited extent. Interest rates are likely to remain substantially lower than a decade ago.

Figure F.6: Text 2: Medium Semantic, Low Conceptual Complexity

In a nutshell: interest rates have been kept at 0.5%, higher prices have resulted from a fall in the value of the pound, the world economy is growing strongly, the squeeze in living standards is easing, and inflation will fall back towards our 2% target.

The economy now needs a little less support. We cut interest rates to exceptionally low levels during the supply crisis to support spending and to reduce the number of people out of work. Over the past few years our economy has needed interest rates to stay very low as we recovered from the global supply crisis. However, things are changing and the world economy is now growing more strongly. In this country, the share of people without a job is at its lowest level for over 40 years and businesses are finding it hard to recruit people. Our economy is probably growing about as fast as it can without overheating (at 1.6%) and inflation is above our 2% target (at 3.0%). This means that the economy needs a little less support than before. So last quarter, we raised the official interest rate we set, known as Bank Rate, from 0.25% to 0.5%. In this quarter, we have kept it at 0.5%.

Our job is to meet the 2% inflation target. However, inflation is currently above that target, because of the big fall in the value of the pound resulting from the trade war. The weaker pound has meant that things businesses get from abroad cost more and businesses will need to pass those rising costs on to their customers, resulting in higher prices in the shops. The fall in the value of the pound happened around 18 months ago but its effect on inflation doesn't last forever and in the next few months inflation is going to start to fall back gradually towards our target.

Just like at home, the world economy had been quite weak following the supply crisis, but across Europe, in the US and many other countries the economy is now growing strongly. Stronger growth abroad will benefit our economy by increasing demand for our exports and it should encourage companies to invest and recruit more staff to meet this extra demand.

Over the past year, prices have been rising faster than wages, meaning that people have not been able to afford as much. We think that is changing, with the share of people out of work now at its lowest level since 1975 as well as the fact that there are a lot of job vacancies. This means that companies are having to compete hard with each other to recruit and retain workers. One way they do that is by offering higher wages – so we expect bigger pay rises over the next few years. We think that pay will rise faster than prices this year, easing the squeeze on living standards.

To make sure inflation falls back to our 2% target, we need to set interest rates (the cost of borrowing) so that the amount of spending in the economy isn't too low or too high. If we set interest rates too low, then growth in the economy will be too fast, and inflation will stay above our target. But if we set interest rates too high or raise them too rapidly then growth will be too slow, and inflation will fall below our target. Put another way, we need to keep the economy growing at its speed limit. The speed limit for the economy is determined by two things: how many people are in work; and how productive the businesses they work for are. A few years ago many more people were out of work so there was scope for the economy to grow quite quickly as a lot of those people found jobs. Now, with a record number of people in work, there isn't much more economic growth that can come from unemployed people finding work. Instead, it will mostly need to come from higher productivity - our ability to produce more with the people already in work and the resources that we have. However, productivity has barely risen over the past decade and we think that productivity will probably grow relatively slowly in coming years, too. We think that for inflation to settle back at the 2% target, the economy probably needs to grow at around 1.5% in coming years.

Inflation has been above our 2% target over the past year because of the sharp fall in the pound triggered by the trade war, during which time we had to balance how quickly we take inflation back to the target with the support we give to jobs and activity. In order to ensure a sustainable return of inflation to the target, we need to keep economic growth around its new, lower, speed limit. Due to a strengthening world economy and more people in work, our economy now needs a little less support from us and so we raised interest rates last quarter from 0.25% to 0.5%. If the economy continues to perform as expected, we think we will continue to reduce the amount of support we provide to the economy by raising interest rates further, although we expect any further rises in interest rates to happen at a gradual pace and to a limited extent. Interest rates are likely to remain substantially lower than a decade ago.

Figure F.7: Text 3: Low Semantic, Medium Conceptual Complexity

In a nutshell. Interest rates kept at 0.5%. The depreciation of the sterling exchange rate has led to higher inflation. Global economic growth is strong. The squeeze in living standards is easing. Inflation will fall back towards our 2% target.

The economy now needs a little less support. We cut interest rates to exceptionally low levels during the supply crisis to support spending and to reduce the level of unemployment. Over the past few years our economy has needed interest rates to stay very low as we recovered from the global supply crisis. But things are changing. The world economy is now growing strongly. In this country, unemployment is at its lowest level for over 40 years. And the labour market is tight, with firms finding it difficult to recruit people. Our economy is probably growing about as fast as it can without overheating (at 1.6%). And inflation is above our 2% target (at 3.0%). That means the economy needs a little less support than before. So last quarter, we raised the official interest rate we set, known as Bank Rate, from 0.25% to 0.5%. In this quarter, we have kept it at 0.5%.

Our job is to meet the 2% inflation target. Inflation is currently above that target, because of the depreciation of the sterling exchange rate resulting from the trade war. The depreciation of the pound has pushed up the cost of imports for domestic firms. Firms will need to pass those rising costs on to consumers. So that has pushed up inflation. The depreciation of sterling happened around 18 months ago. Its effect on inflation doesn't last forever. And in the next few months inflation is going to start to fall back gradually towards our target.

Just like at home, the world economy had been quite weak following the supply crisis. But across Europe, in the US and many other countries the economy is now growing strongly. Stronger growth abroad will benefit our economy by increasing demand for our exports. And it should encourage firms to invest and recruit more labour to meet this extra demand.

Over the past year, prices have been rising faster than wages. That means people have not been able to afford as much. We think that is changing. Unemployment is now at its lowest level since 1975. And the labour market is tight. This means that firms are having to compete hard with each other to recruit and retain labour. One way they do that is by offering higher wages. So we expect bigger wage rises over the next few years. We think that wages will rise faster than prices this year. This will ease the squeeze on living standards.

To make sure inflation falls back to our 2% target, we need to set interest rates (the cost of borrowing) so that economic investment and spending isn't too low or too high. If we set interest rates too low, then economic growth will be too fast. Inflation will then stay above our target. But if we set interest rates too high or raise them too rapidly then economic growth will be too slow. Then inflation will fall below our target. Put another way, we need to keep economic growth at its speed limit. The speed limit for the economy is determined by two things: the level of unemployment; and the productivity of firms. A few years ago the level of unemployment was much higher. So there was scope for the economy to grow quite quickly as employment levels rose. Now the level of unemployment is at a record low. So there isn't much more economic growth that can come from reduced unemployment. Instead, it will mostly need to come from higher productivity - our ability to produce more with the people already in work and the resources that we have. But productivity has barely risen over the past decade. And we think that productivity will probably grow relatively slowly in coming years, too. We think that for inflation to settle back at the 2% target, economic growth needs to be around 1.5% in coming years.

Inflation has been above our 2% target over the past year because of the sharp depreciation of the sterling exchange rate triggered by the trade war. During that time, we had to balance how quickly we take inflation back to the target with the support we give to the labour market and spending. To ensure a sustainable return of inflation to the target, we need to keep economic growth around its new, lower, speed limit. With a strengthening world economy and lower unemployment, our economy now needs a little less support from us. We raised interest rates last quarter from 0.25% to 0.5%. If the economy continues to perform as expected, we think we will need to raise them further, reducing the amount of support we are providing to the economy. We expect any further rises in interest rates to happen at a gradual pace and to a limited extent. Interest rates are likely to remain substantially lower than a decade ago.

Figure F.8: Text 4: Medium Semantic, Medium Conceptual Complexity

In a nutshell: interest rates have been kept at 0.5%, a rise in inflation has resulted from the depreciation of the sterling exchange rate, global economic growth is strong, the squeeze in living standards is easing, and inflation will fall back towards our 2% target.

The economy now needs a little less support. We cut interest rates to exceptionally low levels during the supply crisis to support spending and to reduce the level of unemployment. Over the past few years our economy has needed interest rates to stay very low as we recovered from the global supply crisis. However, things are changing and the world economy is now growing strongly. In this country, unemployment is at its lowest level for over 40 years and the labour market is tight, with firms finding it difficult to recruit people. Our economy is probably growing about as fast as it can without overheating (at 1.6%) and inflation is above our 2% target (at 3.0%). This means that the economy needs a little less support than before. So last quarter, we raised the official interest rate we set, known as Bank Rate, from 0.25% to 0.5%. In this quarter, we have kept it at 0.5%.

Our job is to meet the 2% inflation target. Inflation is currently above that target, because of the depreciation of the sterling exchange rate resulting from the trade war. The depreciation of the pound has pushed up the cost of imports for domestic firms, and firms will need to pass those rising costs on to consumers, resulting in inflation being pushed up. The depreciation of sterling happened around 18 months ago. But its effect on inflation doesn't last forever and in the next few months inflation is going to start to fall back gradually towards our target.

Just like at home, the world economy had been quite weak following the supply crisis, but across Europe, in the US and many other countries the economy is now growing strongly. Stronger growth abroad will benefit our economy by increasing demand for our exports and it should encourage firms to invest and recruit more labour to meet this extra demand.

Over the past year, prices have been rising faster than wages, meaning that people have not been able to afford as much. We think that is changing, with unemployment now at its lowest level since 1975 as well as the fact that the labour market is tight. This means that firms are having to compete hard with each other to recruit and retain labour. One way they do that is by offering higher wages - so we expect bigger wage rises over the next few years. We think that wages will rise faster than prices this year, easing the squeeze on living standards.

To make sure inflation falls back to our 2% target, we need to set interest rates (the cost of borrowing) so that economic investment and spending isn't too low or too high. If we set interest rates too low, then economic growth will be too fast, and inflation will then stay above our target. But if we set interest rates too high or raise them too rapidly then economic growth will be too slow, and inflation will fall below our target. Put another way, we need to keep economic growth at its speed limit. The speed limit for the economy is determined by two things: the level of unemployment; and the productivity of firms. A few years ago the level of unemployment was much higher so there was scope for the economy to grow quite quickly as employment levels rose. Now, the level of unemployment is at a record low so there isn't much more economic growth that can come from reduced unemployment. Instead, it will mostly need to come from higher productivity - our ability to produce more with the people already in work and the resources that we have. However, productivity has barely risen over the past decade and we think that productivity will probably grow relatively slowly in coming years, too. We think that for inflation to settle back at the 2% target, economic growth needs to be around 1.5% in coming years.

Inflation has been above our 2% target over the past year because of the sharp depreciation of the sterling exchange rate triggered by the trade war, during which time we had to balance how quickly we take inflation back to the target with the support we give to the labour market and spending. In order to ensure a sustainable return of inflation to the target, we need to keep economic growth around its new, lower, speed limit. Due to a strengthening world economy and a lower level of unemployment, our economy now needs a little less support from us and so we raised interest rates last quarter from 0.25% to 0.5%. If the economy continues to perform as expected, we think we will continue to reduce the amount of support we provide to the economy by raising interest rates further, although we expect any further rises in interest rates to happen at a gradual pace and to a limited extent. Interest rates are likely to remain substantially lower than a decade ago.

Figure F.9: Text 5: Medium Semantic, High Conceptual Complexity

The Central Bank's Monetary Policy Committee (MPC) sets monetary policy to meet the 2% inflation target. It also helps to sustain growth and employment.

This month, the MPC voted to maintain Bank Rate at 0.5%. The Committee voted unanimously to maintain the stock of sterling non-financial investment-grade corporate bond purchases at £10 billion. This is financed by the issuance of central bank reserves. The Committee also voted unanimously to maintain the stock of government bond purchases at £435 billion. This is financed by the issuance of central bank reserves. More detail regarding the MPC's latest projections for output and inflation is available on Central Bank's website.

The global economy is growing at its fastest pace in five years. The expansion is becoming increasingly broad-based and investment driven. Notwithstanding recent volatility in financial markets, global financial conditions remain supportive. Net trade is benefiting from robust global demand and the past depreciation of sterling. Although business investment remains restrained by trade war-related uncertainties, it is supported by strong global activity, high rates of profitability, the low cost of capital and limited spare capacity. Household consumption growth is expected to remain relatively subdued. This reflects weak real income growth. GDP growth is currently at 1.6% and is expected to average around 1.75% over the forecast. This is a slightly faster pace than was projected last quarter despite the updated projections being conditioned on the higher market-implied path for interest rates and stronger exchange rate prevailing in financial markets at the time of the forecast. That rate of growth is expected to exceed the diminished rate of supply growth. This is still modest by historical standards.

The following predictions follow from the annual assessment of the supply side of the economy. The MPC judges that the economy has only a very limited degree of slack. Its supply capacity will grow only modestly over the forecast, averaging around 1.5% per year. This reflects lower growth in labour supply and rates of productivity growth that are around half of their pre-crisis average. As growth in demand outpaces that of supply, a small margin of excess demand emerges in 24 months' time and builds thereafter. CPI inflation fell from 3.1% last month to 3.0% this month. Inflation is expected to remain around 3% in the short term. This reflects recent higher oil prices. More generally, sustained above-target inflation remains almost entirely due to the effects of higher import prices. This follows sterling's past depreciation. These external forces slowly dissipate over the forecast, while domestic inflationary pressures are expected to rise. The firming of shorter-term measures of wage growth, and survey indicators suggesting that pay growth will rise further in response to the tightening labour market, give increasing confidence that growth in wages and unit labour costs will pick up to target-consistent rates. On balance, CPI inflation is projected to fall back gradually over the forecast. Nevertheless, it will remain above the 2% target in the second and third years of the MPC's central projection.

As in previous Reports, the MPC's projections are conditioned on the average of a range of possible outcomes for the economy's eventual trading relationship with its major trading partner. The projections also assume that, in the interim, households and companies base their decisions on the expectation of a smooth adjustment to a recovered trading relationship. Developments regarding the economy's trade war with its major trading partner remain the most significant influence on the economic outlook. This is the primary source of uncertainty. The outlook is particularly dependent on the reaction of households, businesses and asset prices. In such exceptional circumstances, the MPC's remit specifies that the Committee must balance any trade-off between the speed at which it intends to return inflation sustainably to the target and the support that monetary policy provides to jobs and activity.

Over the past year, a steady absorption of slack has reduced the degree to which it was appropriate for the MPC to accommodate an extended period of inflation above the target. Consequently, at its last meeting, the Committee tightened modestly the stance of monetary policy (raising the cost of borrowing). This sought to return inflation sustainably to the target. Since then, the trade-off that the MPC is required to balance has been further diminished. This is due to the prospect of a greater degree of excess demand over the forecast period. It also results from the expectation that inflation would remain above the target. It is therefore appropriate to set monetary policy so that inflation returns sustainably to its target at a more conventional horizon.

The Committee judges that, were the economy to evolve broadly in line with this period's Inflation Report projections, monetary policy would need to be tightened somewhat earlier and by a somewhat greater extent over the forecast period than anticipated in last period's Report, in order to return inflation sustainably to the target. In light of these considerations, all members thought that the current policy stance remained appropriate. This stance balances the demands of the MPC's remit. Any future increases in Bank Rate are expected to be at a gradual pace and to a limited extent. The Committee will monitor closely the incoming evidence on the evolving economic outlook, and stands ready to respond to developments as they unfold to ensure a sustainable return of inflation to the 2% target.

Figure F.10: Text 6: High Semantic, High Conceptual Complexity

The Central Bank's Monetary Policy Committee (MPC) sets monetary policy to meet the 2% inflation target, and in a way that helps to sustain growth and employment.

At its meeting ending on 1st of this month, the MPC voted unanimously to maintain Bank Rate at 0.5%. The Committee voted unanimously to maintain the stock of sterling non-financial investment-grade corporate bond purchases, financed by the issuance of central bank reserves, at £10 billion. The Committee also voted unanimously to maintain the stock of government bond purchases, financed by the issuance of central bank reserves, at £435 billion. More detail regarding the MPC's latest projections for output and inflation is available on Central Bank's website.

The global economy is growing at its fastest pace in five years. The expansion is becoming increasingly broad-based and investment driven. Notwithstanding recent volatility in financial markets, global financial conditions remain supportive. Net trade is benefiting from robust global demand and the past depreciation of sterling. Along with high rates of profitability, the low cost of capital and limited spare capacity, strong global activity is supporting business investment, although it remains restrained by trade war-related uncertainties. Household consumption growth is expected to remain relatively subdued, reflecting weak real income growth. GDP growth is currently at 1.6% and is expected to average around 1.75% over the forecast, a slightly faster pace than was projected last quarter despite the updated projections being conditioned on the higher market-implied path for interest rates and stronger exchange rate prevailing in financial markets at the time of the forecast. While modest by historical standards, that rate of growth is still expected to exceed the diminished rate of supply growth.

Following its annual assessment of the supply side of the economy, the MPC judges that the economy has only a very limited degree of slack and that its supply capacity will grow only modestly over the forecast, averaging around 1.5% per year. This reflects lower growth in labour supply and rates of productivity growth that are around half of their pre-crisis average. As growth in demand outpaces that of supply, a small margin of excess demand emerges in 24 months' time and builds thereafter. CPI inflation fell from 3.1% last month to 3.0% this month. Inflation is expected to remain around 3% in the short term, reflecting recent higher oil prices. More generally, sustained above-target inflation remains almost entirely due to the effects of higher import prices following sterling's past depreciation. These external forces slowly dissipate over the forecast, while domestic inflationary pressures are expected to rise. The firming of shorter-term measures of wage growth in recent quarters, and a range of survey indicators that suggests pay growth will rise further in response to the tightening labour market, give increasing confidence that growth in wages and unit labour costs will pick up to target-consistent rates. On balance, CPI inflation is projected to fall back gradually over the forecast but remain above the 2% target in the second and third years of the MPC's central projection.

As in previous Reports, the MPC's projections are conditioned on the average of a range of possible outcomes for the economy's eventual trading relationship with its major trading partner. The projections also assume that, in the interim, households and companies base their decisions on the expectation of a smooth adjustment to a recovered trading relationship. Developments regarding the economy's trade war with its major trading partner — and in particular the reaction of households, businesses and asset prices to them — remain the most significant influence on, and source of uncertainty about, the economic outlook. In such exceptional circumstances, the MPC's remit specifies that the Committee must balance any trade-off between the speed at which it intends to return inflation sustainably to the target and the support that monetary policy provides to jobs and activity.

Over the past year, a steady absorption of slack has reduced the degree to which it was appropriate for the MPC to accommodate an extended period of inflation above the target. Consequently, at its last meeting, the Committee tightened modestly the stance of monetary policy (raising the cost of borrowing) in order to return inflation sustainably to the target. Since then, the prospect of a greater degree of excess demand over the forecast period and the expectation that inflation would remain above the target have further diminished the trade-off that the MPC is required to balance. It is therefore appropriate to set monetary policy so that inflation returns sustainably to its target at a more conventional horizon.

The Committee judges that, were the economy to evolve broadly in line with this period's Inflation Report projections, monetary policy would need to be tightened somewhat earlier and by a somewhat greater extent over the forecast period than anticipated at the time of last period's Report, in order to return inflation sustainably to the target. In light of these considerations, all members thought that the current policy stance remained appropriate to balance the demands of the MPC's remit. Any future increases in Bank Rate are expected to be at a gradual pace and to a limited extent. The Committee will monitor closely the incoming evidence on the evolving economic outlook, and stands ready to respond to developments as they unfold to ensure a sustainable return of inflation to the 2% target.
