Introduction

Data Empirical framework and estimation Empirical results Heterogeneity across hospitals Estimating returns to medical spending

Motivation

- Medical expenditures are high, increasing
- Do the benefits of additional expenditures exceed their costs?
 - Estimates of marginal returns needed to inform policy
- Empirical challenge: sicker patients usually receive more inputs
- This paper:
 - Idea: Compare inputs, outcomes across diagnostic thresholds
 - Our focus: 1500 gram "very low birth weight" threshold
 - Just under 3 pounds, 5 ounces

- 4 同 1 4 日 1 4 日

Introduction

Data Empirical framework and estimation Empirical results Heterogeneity across hospitals Estimating returns to medical spending

Why study at-risk newborns?

- High value of even small mortality reductions
- Recent high-cost expansions in treatment
 - Our time period: 1980s-2000s
- Little evidence on returns to incremental expenditures
 - Average returns appear high (Cutler & Meara 2000)
 - Dearth of randomized trials
- Substantively large portion of health care system
 - Child birth common and expensive
 - Data on census of births available
 - Large sample size to test for effects on mortality

- 4 周 ト 4 月 ト 4 月

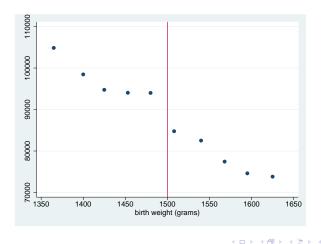

Why study birth weight thresholds?

- Do not represent "real" breaks in underlying health risk
 - "...designation of very low birth weight infants as those weighing 1,500 grams or less reflected convention rather than biologic criteria" (Institute of Medicine 1985)
- Birth weight very near threshold "as good as random"
 - Pre-delivery birth weight estimates imprecise
 - Empirically, no evidence of small-scale manipulation
- A priori plausible to affect treatment
 - Familiar to physicians (e.g. Cloherty & Stark)
 - Reflected in diagnosis, billing codes
 - Empirically, appear to affect treatment provision

Preview of results: One-year mortality

< ∃⇒

Image: A = A

Preview of results: Estimating marginal returns

- Take hospital charges as best available summary measure
- Scale hospital charges by cost-to-charge ratio
- Assume costs fully capture impact of "VLBW" on mortality
- Implied cost of saving statistical life of a newborn with birth weight ${\sim}1500$ grams is on the order of \$550,000 (2006 dollars)

Mortality by birth weight Treatment by birth weight Additional datasets Summary statistics

Data: Mortality by birth weight

Mortality by birth weight: "Nationwide data"

- NCHS linked birth & death certificate data
- Census of US births: 1983-1991, 1995-2002
- \sim 66 million total births
- \circ \sim 200,000 births within 3oz of 1500 grams
- Rich set of covariates (*e.g.* gestational age, mother's age)

・ロト ・同ト ・ヨト ・ヨト

Mortality by birth weight Treatment by birth weight Additional datasets Summary statistics

Data: Treatment by birth weight

Treatment by birth weight: "Five-state sample"

- CA OSHPD longitudinal database
 - Census of CA birth hospital discharges: 1991-2002
 - Linked to death certificates
- HCUP State Inpatient Databases
 - AZ, NJ, NY, & MD
 - Census of birth hospital discharges: various years, 1991-2006
 - Not linked to death certificates; mortality from nationwide data
- Combined five-state sample
 - $\bullet~{\sim}10.5$ million total births
 - ${\sim}30{,}000$ births within 3oz of 1500 grams
 - Charges, length of stay, procedure and diagnosis codes

< 口 > < 同 > < 三 > < 三

Mortality by birth weight Treatment by birth weight Additional datasets Summary statistics

Additional datasets

- CMS: Hospital-year cost-to-charge ratios
- AHA annual surveys: NICU availability
- Phibbs et al. (2007): CA NICU availability by quality level

Mortality by birth weight Treatment by birth weight Additional datasets Summary statistics

Summary statistics

Summary statistics in 3oz above 1500 grams ("control group")

- Nationwide data, 1-year mortality: 5.5%
- Five-state sample, hospital charges: \$81,500
- Five-state sample, length of stay: 25 days

Empirical framework

2 Empirical framework and estimation

- 3 Empirical results
- 4 Heterogeneity across hospitals
- 5 Estimating returns to medical spending

Empirical framework

Empirical framework

Standard methods for regression discontinuity analysis (*e.g.* Imbens & Lemieux (2008), Lee & Lemieux (2009))

- Pilot bandwidth: 3oz (85 grams)
 - Results qualitatively similar across a wide range of bandwidths

| 4 同 1 4 三 1 4 三 1

Empirical framework

Empirical framework (2)

- Local linear regressions
 - Triangle kernal: weight decays with distance from 1500 grams
 - Asymptotic standard errors
 - Cheng et al. (1997), Porter (2003)

OLS

- For infant *i* weighing grams *g* in state *s* in year *t*: $Y_i = \alpha_0 + \alpha_1 (VLBW)_i$ $+\alpha_2 (VLBW)_i * (g_i - 1500) + \alpha_3 (1 - VLBW)_i * (g_i - 1500)$ $+\alpha_4 (t_i) + \alpha_5 (s_i) + \alpha_6 (X'_i) + \epsilon_i$
- Robust and Card-Lee (2008) standard errors

Birth weight density and covariates Health outcomes Summary measures of treatment Mechanisms: Differences in types of care Robustness & specification tests

Mechanisms: Differences in types of care

- Procedure codes, focus on common perinatal procedures
 - E.g. Ventilation, NICU admission
- Difficult to find differences in five-state sample
 - Likely lack statistical power to detect differences
- Some weak evidence for two relatively common procedures:
 - Diagnostic ultrasounds (consistent with e.g. Cloherty & Stark)
 - Operations on the heart

Birth weight density and covariates Health outcomes Summary measures of treatment Mechanisms: Differences in types of care Robustness & specification tests

Mechanisms: Any ventilation, five-state sample

Birth weight density and covariates Health outcomes Summary measures of treatment Mechanisms: Differences in types of care Robustness & specification tests

Robustness & specification tests

- Bandwidth sensitivity
 - Results qualitatively similar for a wide range of bandwidths
- Polynomial order sensitivity
 - Results qualitatively similar for higher-order polynomials
- Alternative first stage outcomes
 - log(charges), median charges, including transfers
- Causes of death
 - No statistically significant change in external deaths
 - Largest effects for perinatal conditions (e.g. jaundice)

Birth weight density and covariates Health outcomes Summary measures of treatment Mechanisms: Differences in types of care Robustness & specification tests

Alternative thresholds

Alternative thresholds: Robustness & alternative estimates

- Unexpected jumps: no other convincing differences
- No convincing differences at 2500 grams ("low birth weight")
- No convincing differences at 37 weeks ("premature")
- Some evidence of small-for-gestational-age effects

- 4 回 ト 4 ヨト 4 ヨト

Birth weight density and covariates Health outcomes Summary measures of treatment Mechanisms: Differences in types of care Robustness & specification tests

Results: Summary

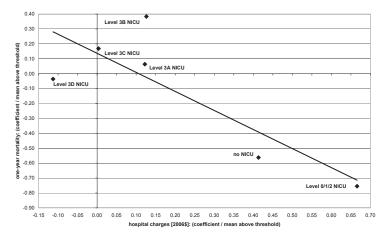

- Preliminaries:
 - Birth frequencies: No evidence of heaping
 - Covariates: Generally smooth across the cutoff
- Reduced form: Mortality
 - 1 percentage point lower one-year mortality (mean = 5.5%)
- First stage: Treatment
 - \$9,000 increase in hospital charges (mean = \$81,500)
 - 1.5 additional days length of stay (mean = 25 days)
- Mechanisms: Weak evidence
- Robustness checks

Comparison to time-series estimates of returns to medical spending Two-sample estimates of marginal returns to medical spending

・ 戸 ト ・ ヨ ト ・ ヨ

Comparison to time-series estimates of returns

Cutler-Meara style calculation

- Within-birth weight changes in cost, mortality over time
- "Long difference" in CA data, 1991-2002
- Implies cost per newborn life of \sim \$1 million

Comparison to time-series estimates of returns to medical spending Two-sample estimates of marginal returns to medical spending

- 4 周 ト 4 月 ト 4 月

Two-sample estimates of marginal returns

- Assume costs fully capture impact of "VLBW" on mortality
- Inoue & Solon (2005) for asymptotic confidence intervals
- Five-state sample: \sim \$615,270 per newborn life
 - = \$4,553/0.0074
 - 95% confidence interval: \$30,000 to \$1.20 million
- All available data: \sim \$527,083 per newborn life
 - = \$3,795/0.0072
 - 95% confidence interval: \$30,000 to \$1.05 million

Comparison to time-series estimates of returns to medical spending Two-sample estimates of marginal returns to medical spending

Some cost-effectiveness benchmarks

- Disability-adjusted value of newborn life: \$2.7 million
 - Cutler & Meara (2000)
- Value of (non-disabled) newborn life: \$3-\$7 million
 - Cutler (2004)

Comparison to time-series estimates of returns to medical spending Two-sample estimates of marginal returns to medical spending

Conclusions

- Medical inputs may be discontinuous across plausibly smooth measures of health risk
- Estimates relevant to "marginally untreated" sub-population
- Here: \sim \$550,000 per statistical life saved (2006 dollars)
- Suggests high returns to medical care for newborns near 1500g
